Covariates for PSM are mainly based on the control variables in the two original regression equations, respectively. And further adjustments are made: First, variables influencing a region to become the pollutant ETS pilot in China are added, including the population density, GDP growth, the percentage of secondary industry, SO_2 intensity, and PM2.5 intensity to reflect cities' characteristics of population pressure, economic development, industrial structure, and pollution (Li and Wen, 2016). Second, *Population* (due to adding *Pop_density*), *pGDP* (due to adding *Pop_density* and *GDP_growth*), and *Ind_structure* (due to adding *Ind2_ratio*) are removed. Third, several control variables of Eq (2) (*Edu_expenditure*, *Sci_expenditure*, and *Emp_structure*) are added as the covariates of PSM for SO_2 emission to reflect the fiscal expenditure on education and technology and the structure of employees.

Variable definition:

Pop_density: Household registered population at year-end/Total land area of the administrative region (persons/sq.km).

GDP_growth: gross regional product(GRP) growth rate (%).

Ind2_ratio: The secondary industry as a percentage to GRP (%).

SO₂_intensity: Industrial SO₂ emissions/gross regional product (GRP).

PM2.5_intensity: PM2.5/gross regional product (GRP).

The neighbor(5) matching within caliper(0.1) is used in cross-sectional matching, and neighbor(2) matching is adopted in phase-by-phase matching. After matching, the propensity score densities of the two groups are highly overlapped ([Figure S 2](#) and [Figure S 3](#)), the requirement of common support is satisfied ([Figure S 4](#)), and p values of the selected covariates in the balance test are not statistically significant ([Table S 2](#)-[Table S 5](#)), which indicates no systematic difference between the treatment and control groups and an effective matching result.

[Table S 6](#) shows the results of PSM-DID in different processing methods. Columns (1)-(3) show PSM-DID: column (1) chooses samples in which the weight values generated by matching are not empty, column (2) selects samples meeting the common support hypothesis with the treatment group, and column (3) adopts weighted regression. Columns (4) and (5) are the results of staggered DID with cross-sectional matching and phase-by-phase matching, respectively. All of these results are significant and consistent with the results of the benchmark regression equations.

Table S 12 Validity test of instrumental variables

Underidentification test (Kleibergen-Paap rk LM statistic):	16.124
Chi-sq(2) P-val =	0.0003
-redundant- option:	
IV redundancy test (LM test of redundancy of specified instruments):	16.124
Chi-sq(2) P-val =	0.0003
Instruments tested: Garbage_disposal Green_space	
Weak identification test (Cragg-Donald Wald F statistic):	7.934
(Kleibergen-Paap rk Wald F statistic):	12.337
Stock-Yogo weak ID test critical values: 10% maximal IV size	19.93
15% maximal IV size	11.59
20% maximal IV size	8.75
25% maximal IV size	7.25
Source: Stock-Yogo (2005). Reproduced by permission.	
NB: Critical values are for Cragg-Donald F statistic and i.i.d. errors.	
Hansen J statistic (overidentification test of all instruments):	0.237
Chi-sq(l) P-val =	0.6265
-endog- option:	
Endogeneity test of endogenous regressors:	51.735
Chi-sq(l) P-val =	0

Note: *Garbage_disposal* denotes the domestic garbage disposal rate and *Green_space* is green space per capita. Data sources are the China City Statistical Yearbook

Kleibergen-Paap rk LM statistic strongly rejects the null hypothesis of under-identification, and the Hansen J statistic (p-value is 0.6265) does not reject the null hypothesis that all instrumental variables are exogenous. The p-value of the instrumental variables redundancy test is significant, rejecting the hypothesis of existing redundancy instrumental variables. Without the assumption of the error term to be independently identically distributed, Kleibergen-Paap rk Wald F statistic is chosen to test the weak instruments. The result indicates that the null hypothesis of weak instruments can be rejected if the real significance level exceeding 15% can be accepted.

Table S 13 Weak instrument robust tests**Weak instrument robust tests and confidence sets for linear IV**H0: $\beta_{\text{industrial_profits:lnS02}} = 0$

Test	Statistic	p-value	Conf. level	Conf. Set
CLR	stat(.) = 53.36	0.0000	95%	[-13.9078, -4.74111]
K	chi2(1) = 50.39	0.0000	95%	[-13.7623, -4.74111]
J	chi2(1) = 3.35	0.0671	95%	[... , -2.99507]
K-J	<n.a. >	0.0000	95% (96%, 99%)	[-14.1988, -4.5956]
AR	chi2(2) = 53.75	0.0000	95%	[... , -4.3046]
Wald	chi2(1) = 18.34	0.0000	95%	[-11.4706, -4.26822]

Confidence sets estimated for 100 points in [-15.0718^-.667018].

Number of obs N = 3821.

Method = **lagrange multiplier (LM)**. Weight on K in K-J test = 0.800.

Tests robust to heteroskedasticity.

Wald statistic in last row is based on ivregress estimation and is not robust to weak instruments.

Weak instrument robust tests based on CLR, K, J, K-J, AR, and Wald all show significant p-value, indicating no weak instruments.
