TABLE A.7: ENRICHED GO-TERMS FOR GENES DOWNREGULATED FOLLOWING THERAPY.	13

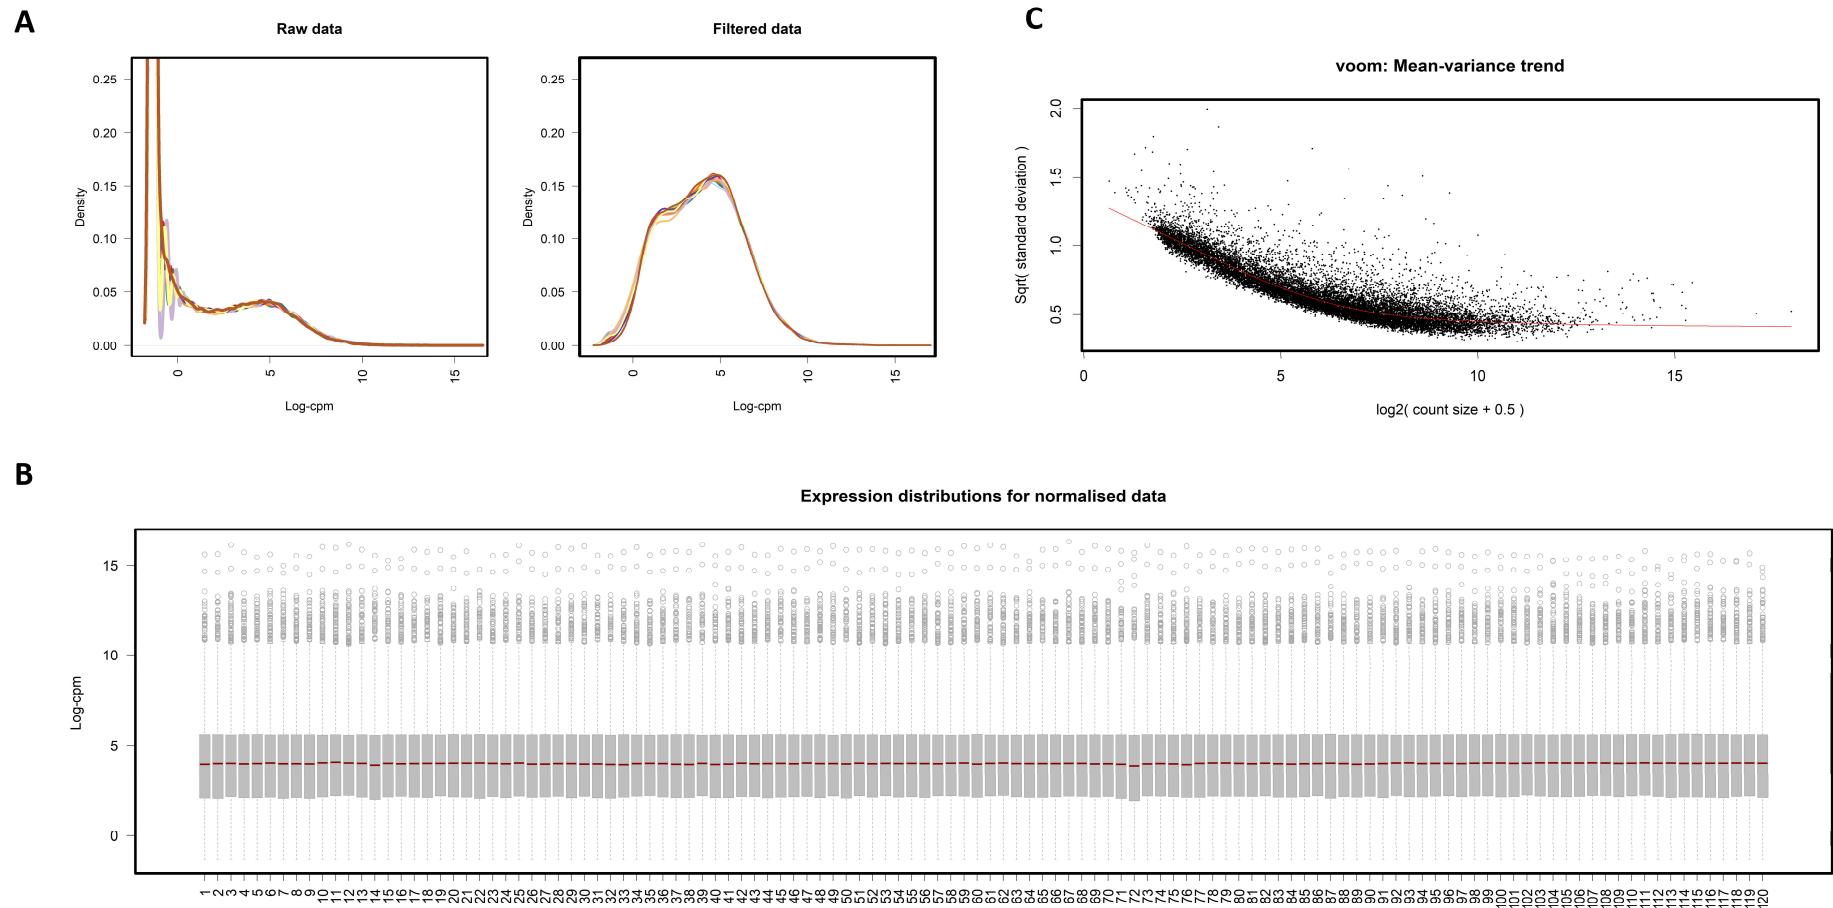

Figure A.1: Effects of preprocessing steps on data quality.

The density of log-CPM values is given for raw data and filtered data (A). Boxplots of log-CPM values visualize the expression distributions for TMM normalized data. Red bars indicate medians (B). A voom plot (c) shows the dependency of log2 mean values and the square-root residual variance of each transcript in normalized data before transformation. The decreasing trend between means and variances indicates sufficient filtering.

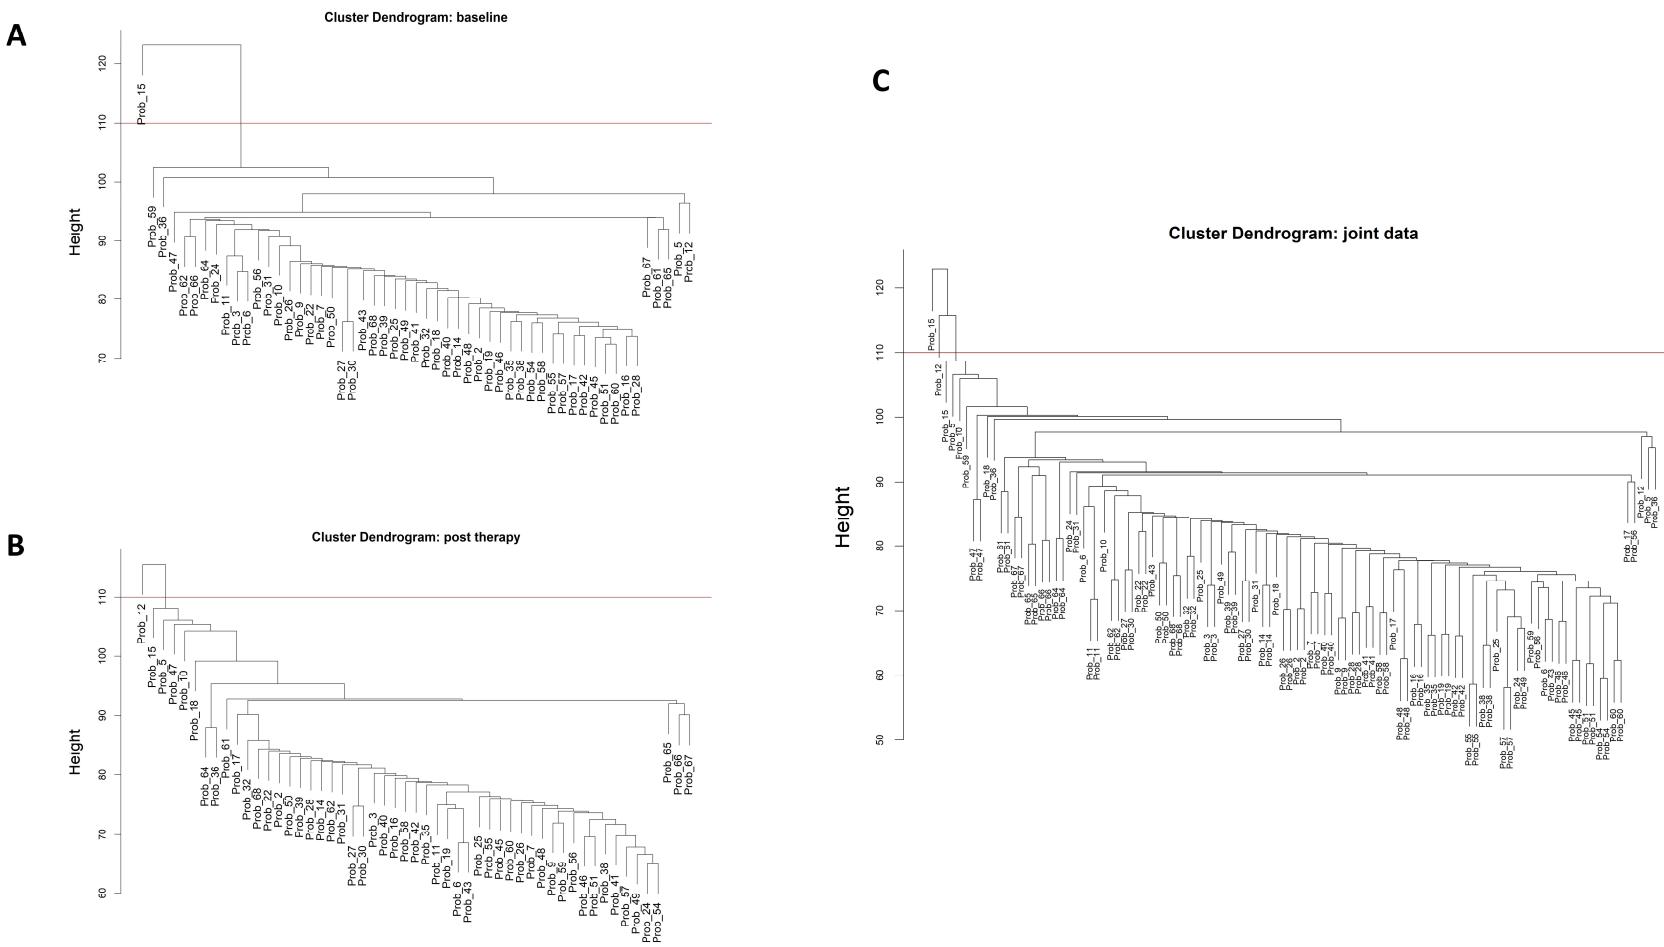

Figure A.2: Outlier detection based on hierarchical clustering with Euclidian distance.

Dendograms for the baseline (A), post therapy (B) and the joint network (C) are depicted. Outliers above the cutoff (red line) were removed from the further analysis.

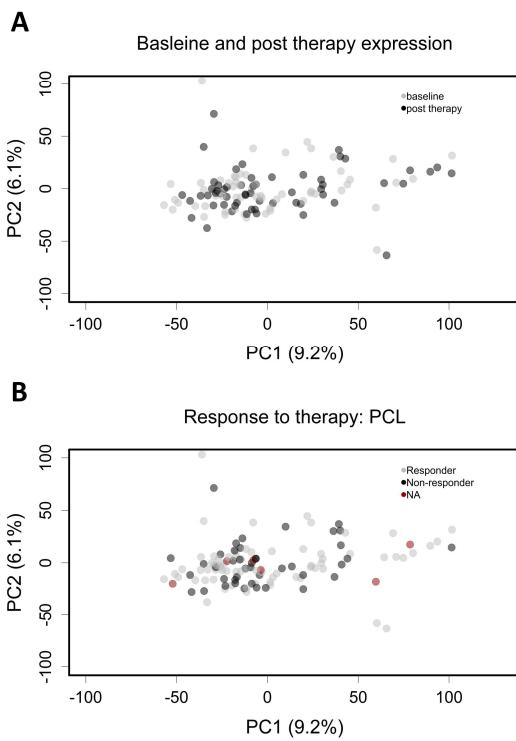

Figure A.3: PCA plots for joint baseline and post therapy gene expression values.

The first PC accounted for 9.2 % and the second PC for 6.1 % of variation in gene expression. Participant's values on the first and second extracted PC are depicted. Points characterize baseline and post therapy measurement (A) and therapy response according to the PCL-5 (B) criteria.

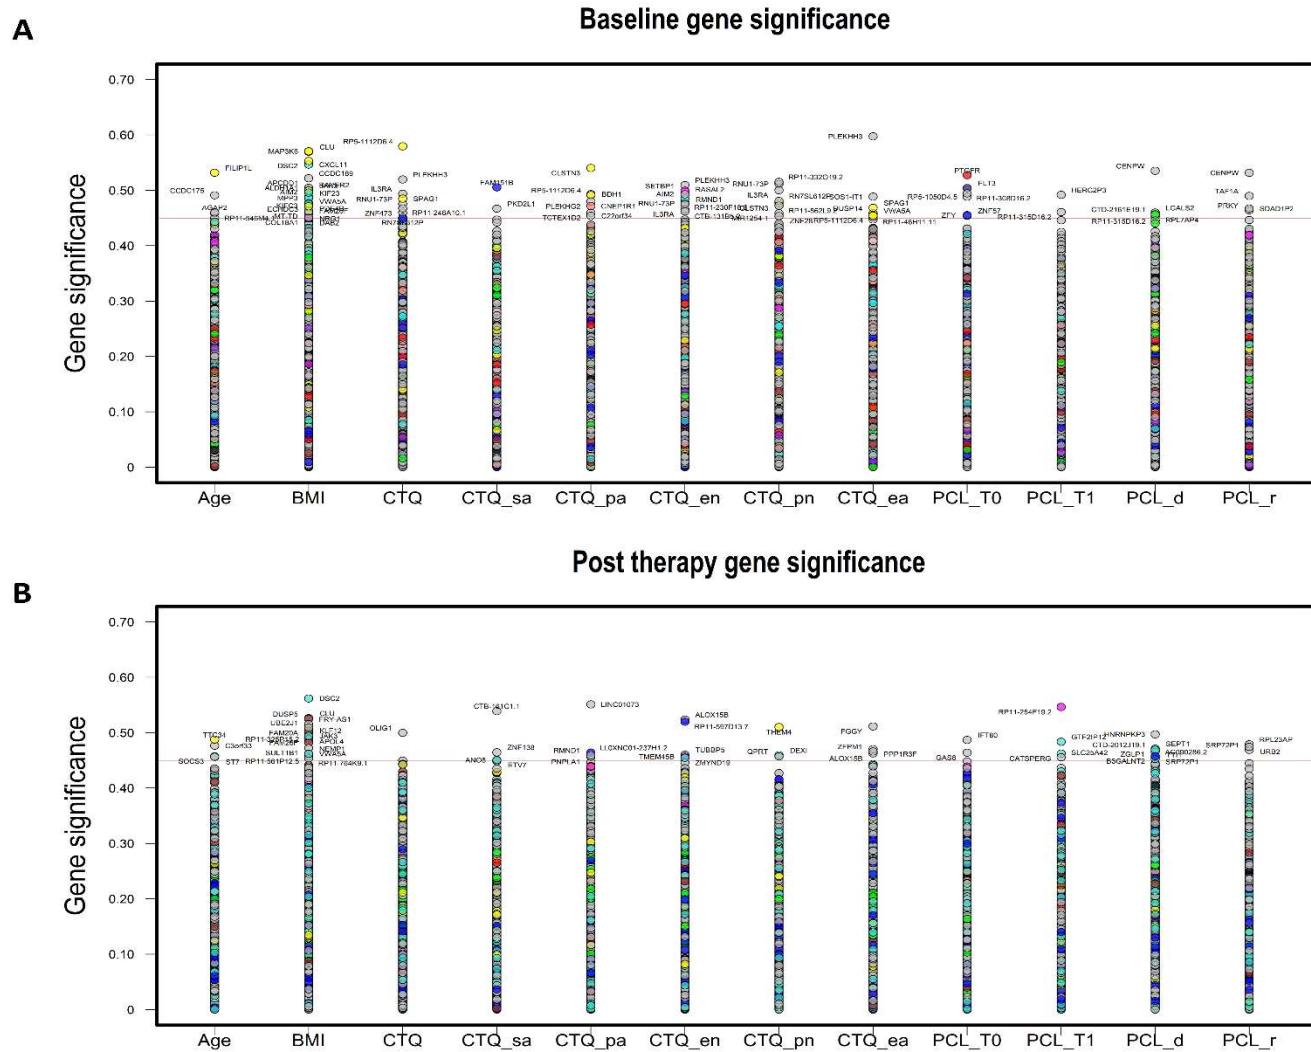

Figure A.4: Baseline and post therapy gene significance

Each point reflects a transcript's absolute correlation with the respective trait of interest (x-axis categories) before (A) and after application of psychotherapy (B). Colors give the module the transcript was assigned to during WGCNA analyses. Gene names are given for correlations surpassing a cutoff of $r = .45$.

Joint data gene significance

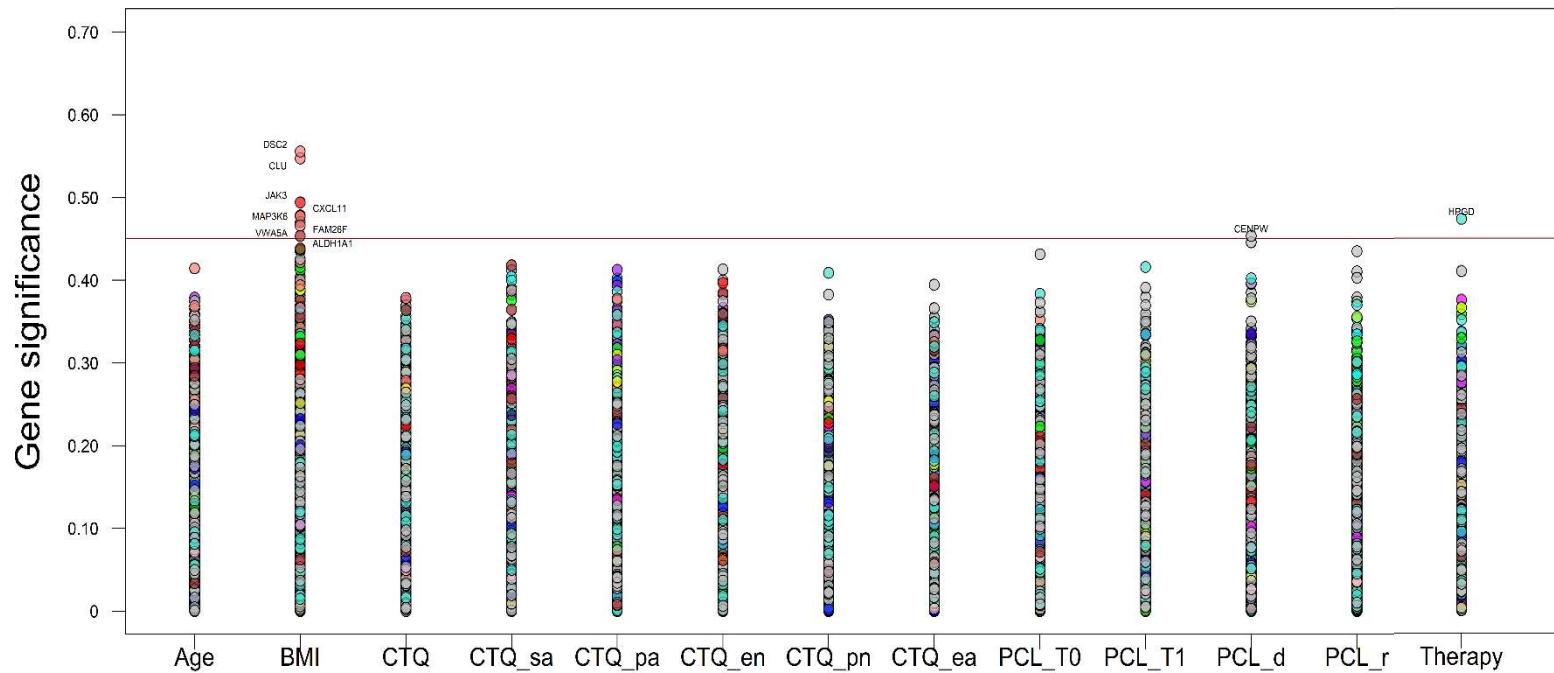

Figure A.5: Joint data gene significance

Each point reflects a transcript's absolute correlation with the respective trait of interest (x-axis categories). Colors give the module the transcript was assigned to during the WGCNA analysis. Gene names are given for correlations surpassing a cutoff of $r = .45$.
