

Appendix A1. Details on Empirical Strategy.

The LLDVE model can be explained as follows: let $Y_{i,t}$ be the dependent variable, where $i = 1, 2, \dots, N$ and $t = 1, 2, \dots, T$ are cross-sectional and time indices and $X_{i,t} = (X_{i,t,1}, X_{i,t,2}, \dots, X_{i,t,d})^T$ is a set of d independent variables; then the basic model can be written as

$$Y_{it} = f_i(t) + X_{it}^T \beta_t + \alpha_i + \epsilon_{it} \quad (4)$$

where we assume $f(t/T) = f_i(t/T)$ for all i is a cross-sectional specific trend function, $\beta_t = \beta(t/T) = (\beta_{t,1}, \dots, \beta_{t,d})^T$ is an unknown time-varying coefficient vector, α_i an unknown individual effect (where $\sum_{i=1}^N \alpha_i = 0$) and ϵ_{it} is assumed to be stationary for each i . The LLDVE technique estimates individual trend functions through fitted residuals, as prescribed by Phillips (2001), under some basic assumptions, namely that (i) ϵ_{it} satisfies martingale differences over time dimensions; (ii) ϵ_{it} are independent of $X_{i,t}$; (iii) ϵ_{it} 's are cross-sectionally dependent for each i ; (iv) $X_{i,t}$ and α_i can be correlated. Using the above assumptions Eq.(4) can be written as

$$Y = f + B(X, \beta) + D\alpha + \epsilon \quad (5)$$

where $Y = (Y_1^T, Y_2^T, \dots, Y_N^T)^T$ with $Y_i = (Y_{i1}, Y_{i2}, \dots, Y_{iT})^T$, $\epsilon = (\epsilon_1^T, \epsilon_2^T, \dots, \epsilon_N^T)^T$ with $\epsilon = (\epsilon_{i1}, \epsilon_{i2}, \dots, \epsilon_{iT})^T$ for all $i = 1, 2, \dots, N$, $f = \bar{I}_N \otimes (f_1, f_2, \dots, f_T)^T$, $\alpha = (\alpha_1, \alpha_2, \dots, \alpha_N)^T$, $D = I_N \otimes \bar{I}_T$ and $B(X, \beta) = (X_{11}^T \beta_1, \dots, X_{1T}^T \beta_T, \dots, X_{N1}^T \beta_1, \dots, X_{NT}^T \beta_T)$, \bar{I}_k is a $k \times 1$ vector of ones and \otimes is the Kronecker product. Assuming $\sum_{i=1}^N \alpha_i = 0$ Eq. (4) can be re-written as

$$Y = f = B(X, \beta) + D_* \alpha_* + \epsilon \quad (6)$$

where $\alpha_* = (\alpha_2, \dots, \alpha_N)^T$ and $D_* = (-\bar{I}_{N-1}, I_{N-1})^T \otimes \bar{I}_T$. The final assumption, $\beta_t = (\beta_1(t/T), \beta_2(t/T), \dots, \beta_d(t/T))^T$ for $t = 1, 2, \dots, T$, provided an unknown smooth function τ with $\tau = t/T \epsilon(0, 1]$ given $f_t = f(t/T)$

Appendix A2. Summary statistics, Tests for cross sectional dependence and unit root

Table A1: Summary Statistics
