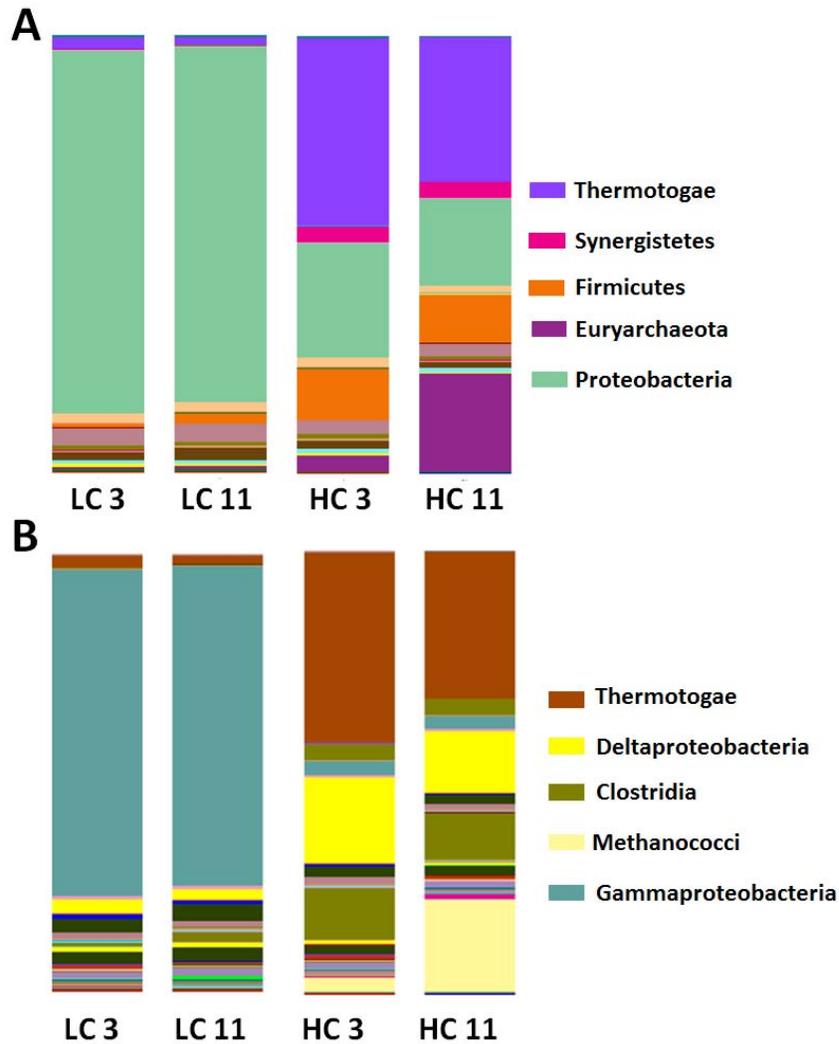

Figure S1. Phylogenetic breakdown of 16S rRNA gene sequences at the (A) phylum level and (B) class level. Partial 16S rRNA gene PCR products were sequenced after barcoding and multiplexing using an Illumina MiSeq. Data were then analyzed using the QIIME pipeline (Caporaso et al. 2010b). Operational Taxonomic Units (OTUs) were generated using UCLUST at the 95% identity level. Alignment to the SILVA small subunit rRNA reference alignment (www.arb-silva.de) was used for classification.

Figure S2.

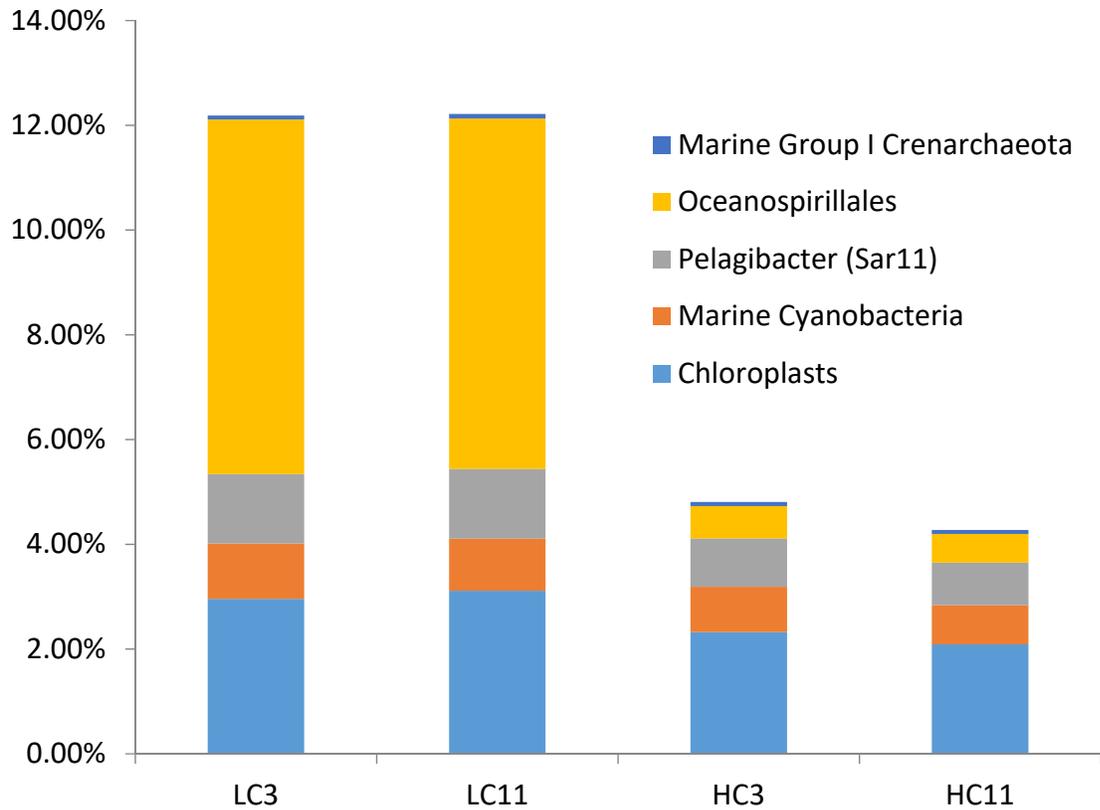

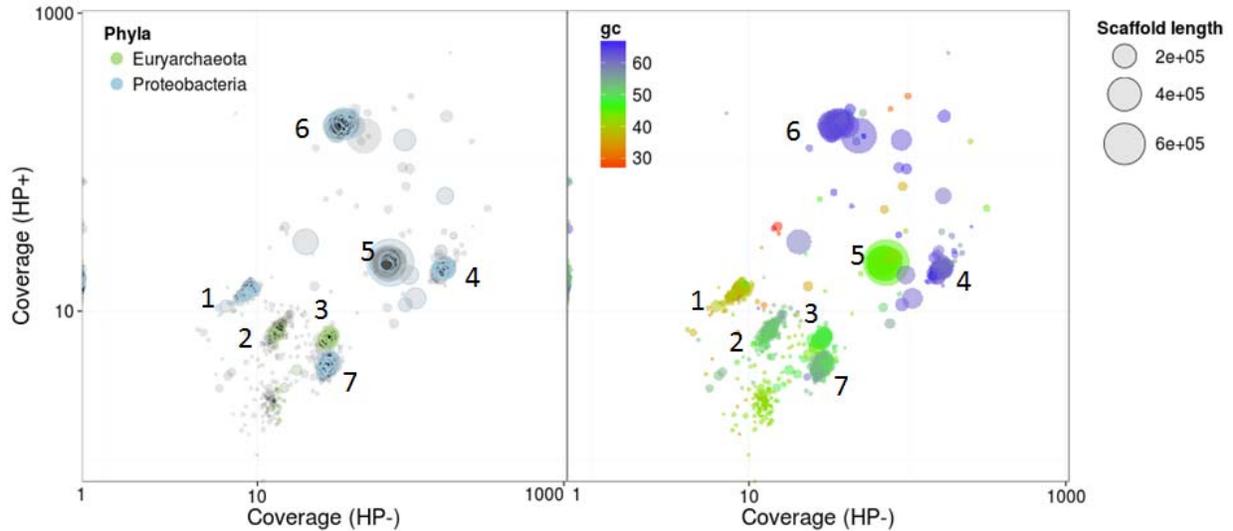

Figure S2. Frequency of diagnostic epipelagic marine taxa in 16S rRNA gene sequence data.

Requisite taxa are common to marine surface waters and are not known to exist in subsurface environments or produced waters. The chloroplast signal originates from a range of Chlorophyte and Chromalveolate marine algal lineages including Heterokonts, Haptophytes and Dinoflagellates, which are similarly diagnostic of marine surface waters.

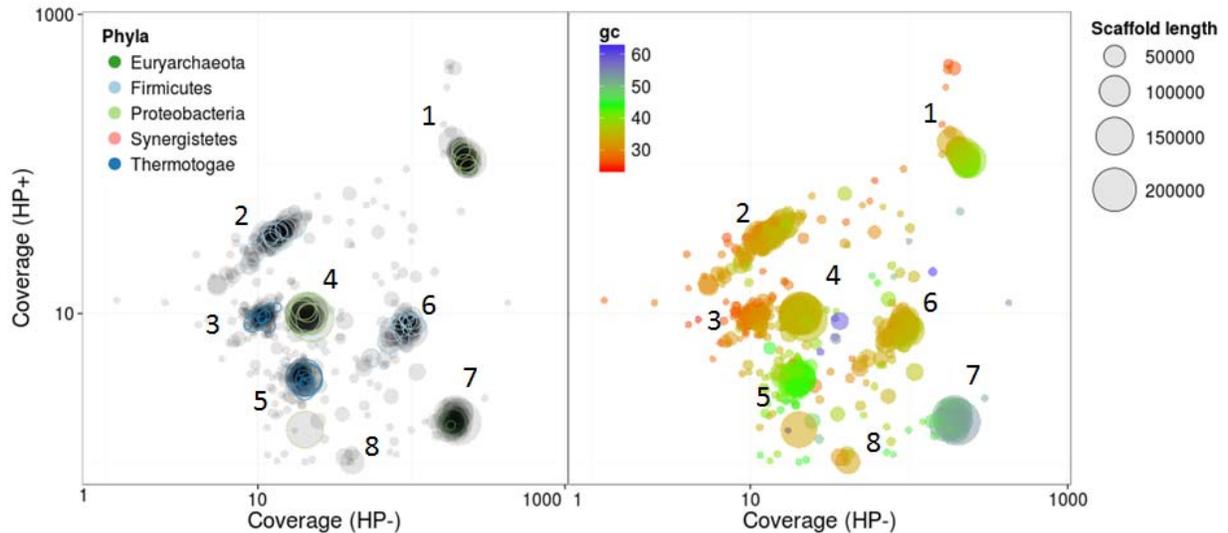

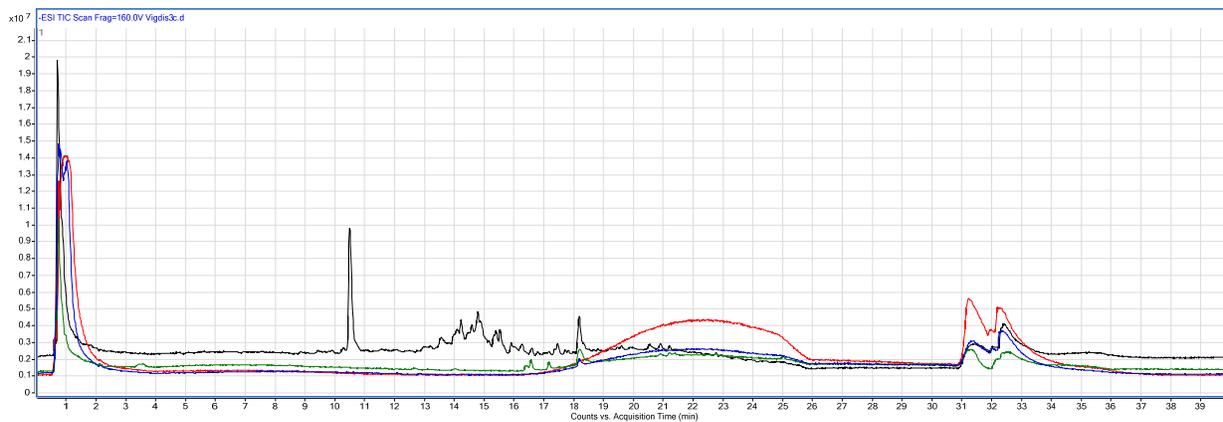

Figure S3. Graphical representation of metagenome data produced via Multimetagenome analysis (Albertsen et al. 2013). Two closely related metagenomes are analyzed in this analysis. Here, the LC3 vs LC11 (A) and HC3 vs HC11 (B) metagenomes were compared. Each contigs frequency is assessed via direct mapping of reads via Bowtie2 to determine coverage (x- and y-axes). HMM analysis of core housekeeping genes is used to determine the phylogenetic affiliation of individual contigs (left panels). Using this, as well as the GC content of contigs (right panels), groups of contigs are identified and extracted. Contig groups are further interrogated via PCA analysis of tetra-nucleotide frequencies to generate final bins (not shown).

Figure S5.

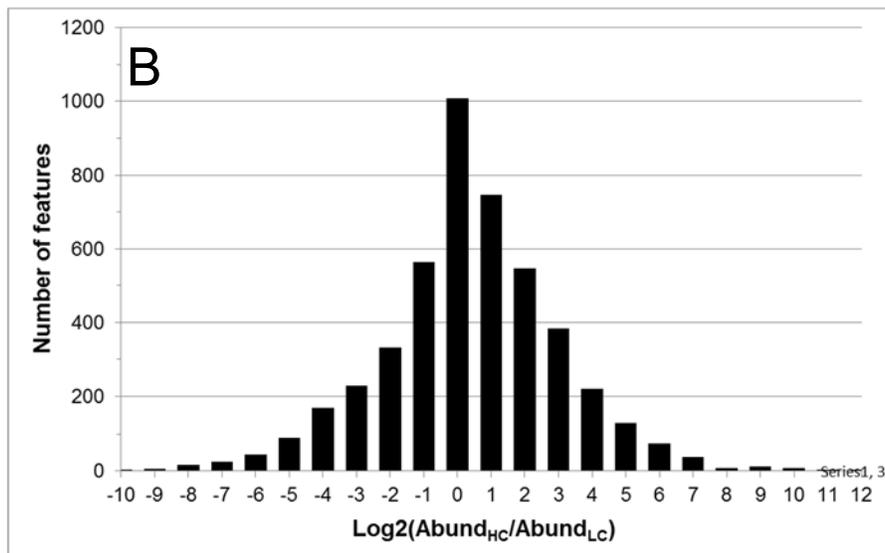

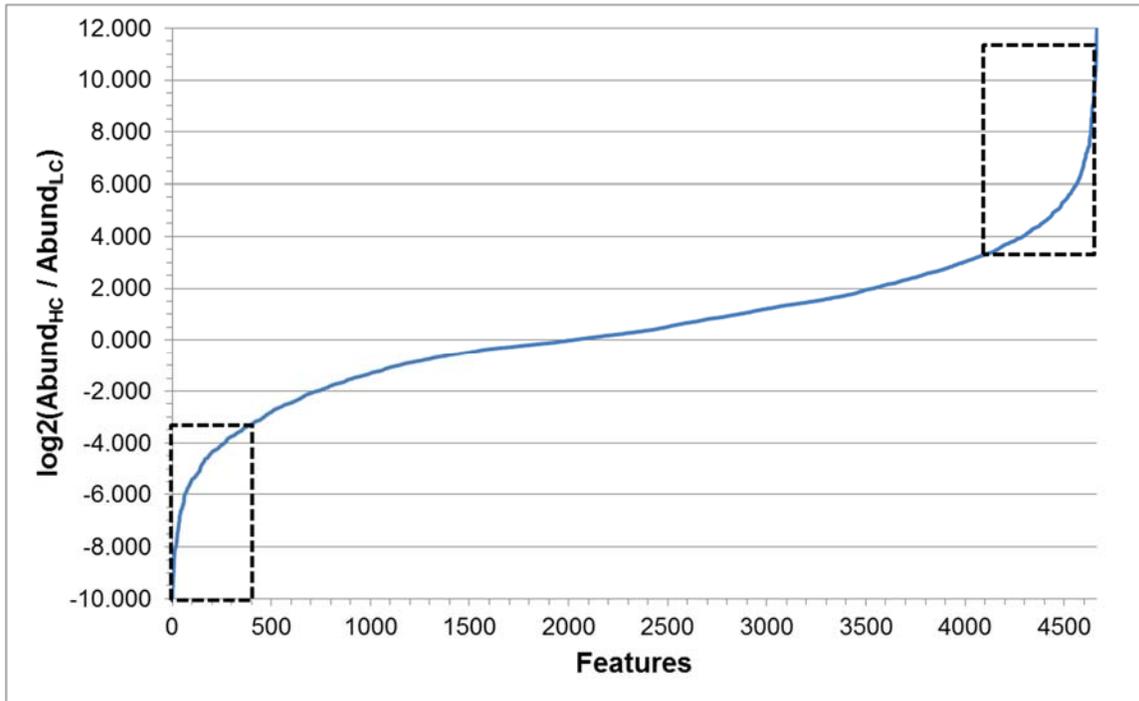

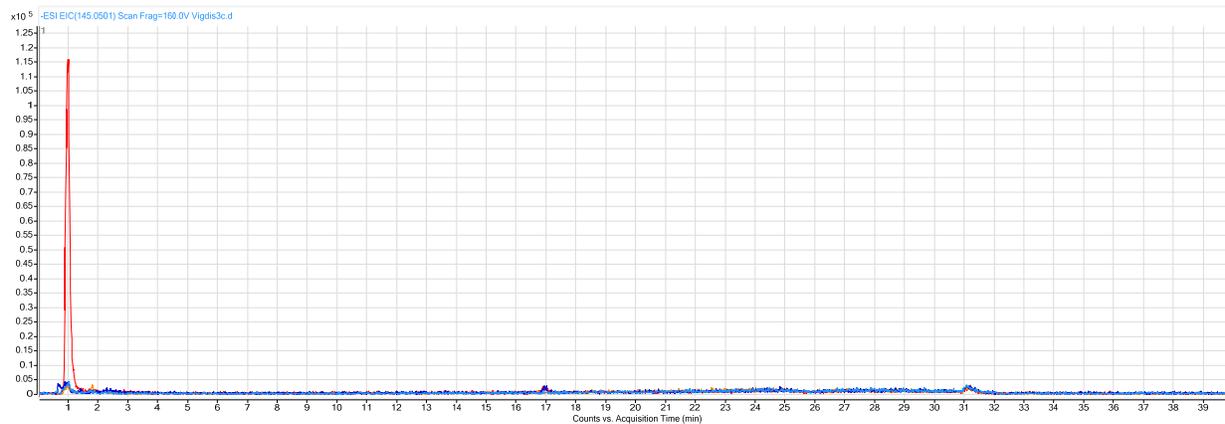

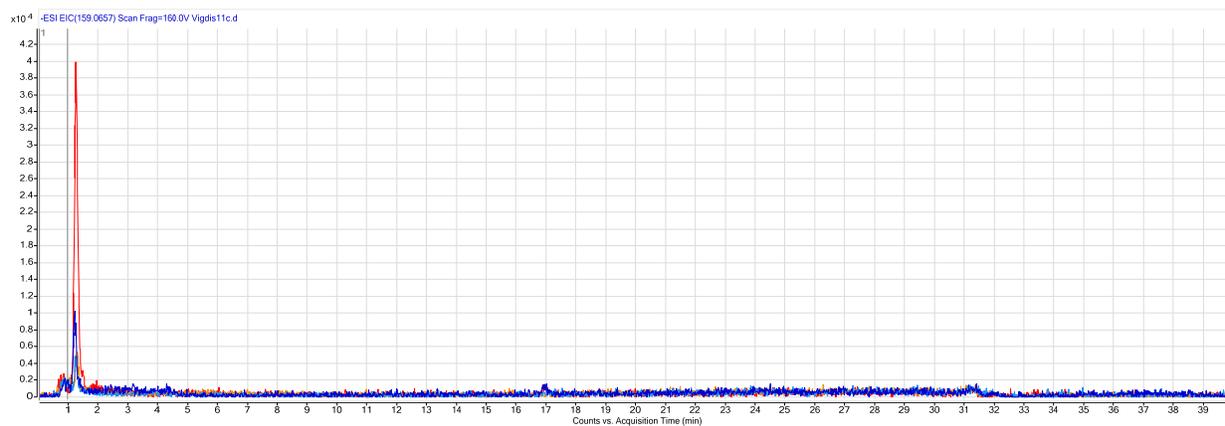

Figure S5. Distribution of log₂ ratios of abundances of features in HC versus LC samples. A) The lower left rectangle encompasses the 389 features that have a more than 10 times higher abundance in the combined LC samples than in the combined HC samples, and the upper right rectangle the 561 features that similarly are more than 10 times more abundant in the HC samples. B) The frequency distribution of log₂ abundance ratios reveals a gradual distribution. For about 50% of the features, the abundance ratio is between 1/3 and 3/1.

For each EIC, all ions of the same mass will be detected, including those derived from the target compound and those derived from any structural isomers. The retention time range is 0 to 40 minutes.

Table S8. Detection of metabolites involved in common metabolic pathways. Pathways are defined as in the KEGG database. The second column shows the combined number of metabolites detected by HPLC/HRMS in positive and negative ion modes and the total number of metabolites listed for that pathway. The right column lists the samples in which the compounds in the respective pathway were preferentially detected. Yellow highlights indicate greater representation in LC samples; green highlights indicate greater representation in HC samples; and “All” indicates that no significant differences in the number of detected metabolites were observed between the LC and HC systems.
