

Relationships describing bending trajectory of mortality from DNS

If some maximal limit bounds congenital individual risks in the born population, then the following approximation may be valid according to the TCIR (Dolejs, 2001; Dolejs, 2003):

$$\mu(x) = \int_0^{r_{max}} c \cdot e^{(-r \cdot x)} dr = c \cdot \left[\frac{e^{(-r \cdot x)}}{-x} \right]_0^{r_{max}} = c \cdot \frac{e^{(-r_{max} \cdot x)}}{-x} - c \cdot \frac{1}{-x} = \frac{\mu_1}{x} \cdot [1 - e^{(-r_{max} \cdot x)}] \quad (7)$$

In the present study, Di decreased by three orders of magnitude, and $S(x)$ was higher than 0.98 at the age of 10 years. Consequently, the changes in the denominator (number of living persons) with age can be neglected due to the changes in the numerator of equation (1). Based on the TCIR, we simultaneously assumed that the distribution of individual congenital risk r can be approximated by the relationship $f(r) = c/r$. Because the numerator is the partial derivative of $S(x)$ with respect to the variable x , the variable r is only in the exponential term. (Variable r represents the denominator in the frequency function $f(r)$, and it is also the result of the partial derivative in the numerator.) Furthermore, if the product $r_{max} \cdot x$ is small in equation (7), then the theoretical mortality rate is approximately constant according to the following relationship (8) (Dolejs, 2001; Dolejs, 2003):

$$\mu(x) = \frac{\mu_1}{x} \cdot [1 - e^{(-r_{max} \cdot x)}] \cong \frac{\mu_1}{x} [1 - (1 - r_{max} \cdot x)] = \mu_1 \cdot r_{max} \quad (8)$$

If a time unit of 1 year is used, and if r is represented per year, then the product $r_{max} \cdot x$ is unitless. The approximation (8) is valid if the product $r_{max} \cdot x$ is very small, relative to 1.
