Note A: Formula for the positive predictive value (PPV) adjusted for the prevalence in a population

A binary classifier is evaluated using the confusion matrix shown below.

	Ground truth is positive	Ground truth is negative
Model predicts positive	True positives (TP)	False positives (FP)
Model predicts negative	False negatives (FN)	True negatives (TN)
	All positives (P) = TP + FN	All negatives (N) = FP + TN

Here, sensitivity is given by TP/P and specificity by TN/N . Note that, because each of these measures only depends on one of the two classes, they are not affected by the prevalence rate in the study population. In contrast, the PPV is affected by the prevalence rate of the positive condition in the study population, because the PPV depends on both classes [$PPV = (TP) / (TP + FP)$]. However, we can re-write this equation so that the PPV becomes explicitly dependent on the prevalence and use the overall prevalence in the population instead of the study prevalence.

$$\begin{aligned} \text{We can then write, } PPV &= \frac{\frac{TP}{P+N}}{\frac{TP}{P+N} + \frac{FP}{P+N}} \\ &= \frac{\frac{TP}{P} \times \frac{P}{P+N}}{\frac{TP}{P} \times \frac{P}{P+N} + \frac{FP}{N} \times \frac{N}{P+N}} \end{aligned}$$

Noting that TP/P is the sensitivity, $P/(P+N)$ is the prevalence, FP/N is $(1 - \text{specificity})$, and $N/(P+N)$ is $(1 - \text{prevalence})$, we derive the following formula:

$$\text{Adjusted PPV} = \frac{(\text{sensitivity} \times \text{prevalence})}{(\text{sensitivity} \times \text{prevalence}) + \{(1 - \text{specificity}) \times (1 - \text{prevalence})\}}$$

, where the PPV is an explicit function of the prevalence of PTSD in the overall population of combat-exposed Veteran men, i.e., 15% (26-28).

Table S1: Effect sizes, areas under the receiver operating characteristic curve (AUCs), and Wilcoxon rank-sum test *p*-values for the 34 features in the entire study population [n = 78 (31 with PTSD)], selected based on the criterion that the lower confidence interval of the AUC exceeded 0.5 on both nights for data from the *training* set alone [n = 47 (18 with PTSD)]. Cells shaded in grey indicate feature clusters. Unshaded cells indicate the 12 independent features. The three features used in the logistic regression model are highlighted in bold-faced text.
