SUPPLEMENTARY MATERIAL: THE EFFECT OF THE SAMPLING FREQUENCIES

2 In this section, we reported a full overview of the results based on different sampling frequen-
3 cies. Based on Table A1, the best regression performance is reached at $f_s = 12 \text{ Hz}$ in the *PB*
4 scheme ($R_{train}^2 = 0.75$, $MAE = 1.83 \text{ weeks}$, $R_{test}^2 = 0.57$) as well as between bradycardias
5 ($R_{train}^2 = 0.68$, $MAE = 1.56 \text{ weeks}$, $R_{test}^2 = 0.59$). During the bradycardia event (*WB*), the best
6 performance is achieved with the spectral features at $f_s = 6 \text{ Hz}$ ($R_{train}^2 = 0.73$, $MAE = 1.9$
7 weeks , $R_{test}^2 = 0.62$). The LASSO selection is also reported for the different sampling frequencies
8 in Table A2.

9 The importance of testing different sampling frequencies was highlighted by Bolea et al., who
10 showed a dependency for nonlinear metrics (such as Sample Entropy) with the resampling fre-
11 quency of the tachogram (Bolea et al., 2016). Based on their results, Bolea et al. concluded that a
12 resampling frequency correction of nonlinear parameters is needed in cardiovascular applications in
13 order to detect meaningful results (such as experiments with body position changes) (Bolea et al.,
14 2016). The employed fractal indices clearly show a increasing trend with an increasing sampling
15 frequency (Section 2.3.3 and Table A3). However, a correction for the sampling frequency was not
16 implemented. The multifractal properties were investigated with different sampling frequencies and
17 our study shows mild differences in term of regression results and correlation with age (Table A3).

Table A1. Linear mixed-effect model performances for the different sampling frequency f_s .

Post-bradycardia (<i>PB</i>) epochs

Table A3. The fractal features are reported in three different age categories and for the investigated sampling frequencies $f_s = [6, 8, 12]$ Hz. The results are reported as median(IQR) for the between-bradycardia and bradycardia periods. IQR stands for *interquartile range*. The symbol ρ stands for the Pearson correlation coefficient. The symbol ** represents a significant correlation with $p \leq 0.01$, and * is used for a significant correlation with $p \leq 0.05$. *n.s.* is used to indicate a non-significant correlation.

SUPPLEMENTARY MATERIAL: OVERVIEW TABLES

Table S1. A detail overview of the recordings of the included patients: the study of each patient ID (PAT_{ID}), the serial number that indicates the recording for each patient (REC_{ID}), the duration of the recording in minutes ($Duration_{Rec}$), average duration of the annotated bradycardias in s for the recording ($Duration_{WB}$), the number of the annotated bradycardias in the recording ($Number_{WB}$), the average RR amplitude during the bradycardia in ms (RR_{WB}), the sampling frequency of the ECG used to derive the tachogram in Hz ($F_{S,ECG}$), postmenstrual age in weeks (PMA) and gestational age in weeks (GA). The last three rows represent the number of recording for each age subgroups (below 32 PMA weeks, between 32 and 36 weeks and above 36 weeks). Blank spaces indicates that bradycardias were not annotated according to the definition in Section ??.

Table S3. The main temporal, spectral and fractal features are reported for the post-bradycardia periods. The results are reported as median(IQR). IQR stands for *interquartile range*. The fractal indices are reported for $f_s = 8 \text{ Hz}$. The symbol ρ stands for the Pearson correlation coefficient. The symbol ** represents a significant correlation with $p \leq 0.01$, and * is used for a significant correlation with $p \leq 0.05$. *n.s.* is used to indicate a non-significant correlation.

Table S6. A detail overview of the average number of beats for the different states period defined in this study: the average duration of the annotated bradycardias (Braydcardia) and the average durations of the between-bradycardia window (Duration *BB*), the post-bradycardia window (Duration *PB*) and the within-bradycardia window (Duration *WB*). Blank spaces indicates that bradycardias were not annotated according to the definition in Section ?? or windows were not available (e.g. there were not enough 10 minutes window between bradycardia events).
