

***Sex-specific Retinal Anomalies Induced by Chronic Social Stress  
in Mice: Supplementary Material***

## Detailed ERG analyses

For both scotopic and photopic recordings, average signals were calculated from all ERG traces collected for each flash stimulation in each mouse using Espion 3.0.1 (Diagnosys LLC, Lowell, MA). To remove OP contamination from the a- and b-wave measurements, low-frequency waves were isolated from the scotopic signals (**Figure 1c**) of each mouse applying a band-stop filter from 75 to 300 Hz using the Butterworth method from the Infinite Impulse Response (IIR) filter tool in OriginPro 2020 (OriginLab Corp., Northampton, MA). Such filtering is promoted by the International society for clinical electrophysiology of vision (McCulloch et al., 2015) and was previously used in mice by Lavoie, et al. (Lavoie et al., 2014). Conversely, OPs were extracted from both scotopic and photopic ERGs (**Figure 1 d, e**) of each mouse by removing the low frequencies applying a digital band-pass filtering from 75 to 300 Hz (Lavoie et al., 2014; McCulloch et al., 2015) using the Fast Fourier Transform (FFT) tool from the same software. Amplitudes and implicit times of the scotopic and photopic OPs and scotopic a- and b-waves were measured for each resultant wave using OriginPro 2020 (OriginLab Corp., Northampton, MA). The photopic a- and b-waves were measured from the non-filtered signals using the same software. Note that mice were identified by identifier (ID) numbers during all ERG recordings as well as during the signal processing and assessment in order to generate unbiased data. Outliers for each group were then identified using the GraphPad's QuickCales Grubb's test (GraphPad Software Inc., San Diego, CA) and removed when applicable. Statistical analyses were performed for every luminance step on the total OP amplitude (summation of the peak amplitude measured in the first four OPs and first two OPs in scotopic and photopic conditions, respectively) and the a- and b-wave amplitudes and implicit times with SPSS Statistics 27.0 (IBM Corp., Armonk, NY). Scotopic and photopic ERGs were analyzed separately.

The ERG data was presented as the mean and standard error of each parameter. For both scotopic and photopic ERGs, a linear mixed model analysis was performed to compare male and female susceptible, resilient, and control mice at baseline using the recorded luminance step (scotopic: -0.020 to 2.859 log cd.s/m<sup>2</sup>; photopic: 0.885 to 2.859 log cd.s/m<sup>2</sup>) as a covariate. Post hoc were analyzed using Fisher's least significant difference (LSD) multiple comparisons test. Variations in ERG parameters for each sex were then tested separately using linear mixed model analyses in which phenotype (susceptible, resilient, and control) and time of assessment (pre-stress versus post-stress) were included as main factors. Mean and standard error of each parameter were presented for each distinct level combination of the factors. The LSD multiple comparisons test was used in post hoc. All p-values under .05 were considered as significant.

**Supplemental Tables 9-13.** Summary of the two-way mixed model ANOVA results from all recorded densities of light for the photopic condition comparing means and standard errors from susceptible, resilient, and control mice. The tables also display the fixed effect of each interaction from the analysis. *M* = mean; *SE* = standard error, *P* = p-value, *F* = Fisher's statistic. Significance is set at .05.

**Supplemental Table 14.** Summary of the estimates and 95% confidence intervals of each ERG parameter in the scotopic condition at 1.89 log cd.s/m<sup>2</sup> and in the photopic condition at 2.86 log cd.s/m<sup>2</sup> during the baseline (pre) and after the stress (post) in all groups of male mice (susceptible, resilient, and control). Confidence intervals were obtained from the LSD multiple comparisons test. M = mean; SE = standard error, CI = confidence interval.
