doi: 10.3389/fmicb.2016.01649

BACKGROUND

Enterobacter aerogenes is a motile, non-spore forming, Gram-negative bacteria from the *Enterobacteriaceae* family. *Enterobacter* spp. have emerged as multidrug-resistant (MDR) nosocomial bacteria, especially in intensive care units (Loival et al., 1999; Piagnerelli et al., 2002). Therefore, over the last decade *Enterobacter* spp. were included in the ESKAPE group, which also comprises *Enterococcus faecium*, *Staphylococcus aureus*, *Klebsiella pneumoniae*, *Acinetobacter baumannii*, and *Pseudomonas aeruginosa* (Rice, 2008; Boucher et al., 2009). Further, bloodstream infections with MDR *E. aerogenes* have been associated with high mortality rates (Davin-Regli and Pagés, 2015).

Hospital outbreaks due to *E. aerogenes* have been reported in Europe since the mid-1990s and have been related to an epidemic extended-spectrum beta-lactamase (ESBL) clone carrying the *blaTEM-24* gene (Bosi et al., 1999; Galdbart et al., 2000; Dumarche et al., 2002; Salso et al., 2003). Constitutive AmpC a (beta-lactamase) overexpression is the major cephalosporin resistance mechanism in *Enterobacter* spp., happening more often than the acquisition of *ampC* genes through the activity of mobile genetic elements (Perez-Perez and Hanson, 2002). Further, the increased expression of ESBLs led to the adoption of carbapenems to treat *E. aerogenes* infections (Perez-Perez and Hanson, 2002; Davin-Regli and Pagés, 2015).

Carbapenems have been considered the antibiotic of choice for treating patients infected with ESBL-producing *Enterobacteriaceae* (Vardakas et al., 2012). However, emergence of carbapenem-resistant *E. aerogenes* isolates during carbapenem therapy of hospitalized patients (Chen et al., 2008), cases of sepsis due to carbapenem-resistant *E. aerogenes* after liver transplantation (Chen et al., 2009) and hospital disseminations of carbapenemase-producing *E. aerogenes* have been recently reported in several countries (Lavigne et al., 2013; Kuai et al., 2014; Qin et al., 2014; Pulcrano et al., 2016). Acquisition and expression of carbapenemases constitute the primary mechanism underlying the development of carbapenem resistance (Rapp and Urban, 2012). Nevertheless, loss of function mutations in porin genes and increased expression of efflux pumps or their regulators have also been associated with carbapenem resistance profiles (Pradel and Pages, 2002; Yigit et al., 2002; Bornet et al., 2003).

Broad-spectrum antimicrobial-resistant *E. aerogenes* isolates, some resistant to carbapenems (Qin et al., 2014) and last-line therapeutic options such as colistin (Diene et al., 2013),

have been responsible for outbreaks in the United States of America (Wong et al., 2010), China (Qin et al., 2014), Japan (Goshi et al., 2002), France (Diene et al., 2013), Fiji (Narayan et al., 2009) and Brazil (Tuon et al., 2015). However, few reports related to *E. aerogenes* epidemiology, pathogenesis, and molecular characterization have been conducted in Brazil. Recently, five panresistant *E. aerogenes* isolates were reported in a Brazilian teaching hospital, resulting in a high mortality rate (37.5%) among 16 infected patients (Tuon et al., 2015). We have observed high prevalence (>20%) of ESBL-producing *Enterobacteriaceae* spp., in particular *K. pneumoniae* and *E. aerogenes*, in our hospital since 2003 (Nogueira Kda et al., 2014, 2015). Previous molecular characterization studies conducted over 5 years in our hospital showed high prevalence of *bla*_{CTX-M2}, -M15, -M59, *blaSHV*-2 and *blaTEM* genes in *Enterobacter* spp. isolates (Nogueira Kda et al., 2014, 2015). The presence of *blaPER*-2 was also detected in a few isolates (Nogueira Kda et al., 2014, 2015). Given the severity of *E. aerogenes* infections and the urgent need to better understand the genetic basis of multidrug resistance, here we report the whole-genome sequencing and resistance gene repertoire of four multidrug-resistant *E. aerogenes* isolated from hospitalized patients in Brazil.

METHODS

Sample Collection and Identification

E. aerogenes isolates C10, D2, D3, and E9 were obtained between 2006 and 2012 from patients hospitalized in wards or intensive care units at the Hospital de Clínicas of the Universidade Federal do Paraná (Curitiba, Brazil). The main selection criterion for genome sequencing was the MDR phenotype, particularly in carbapenem resistant isolates. The negative laboratory tests for carbapenemases were also taken into account, as divergent enzymes or alternative resistance mechanisms could be relevant to the observed MDR phenotypes. C10 and D2 samples were isolated from different body sites of the same patient. Isolates were grown in selective medium with an ertapenem disk (10 µg) and stored at -80°C in trypticase soy broth containing glycerol 15%. Identification of isolates was performed using Vitek® 2 Compact (BioMérieux S.A., Marcy l'Etoile, France) and by mass spectrometry using Microflex LT instrument (Bruker Daltonics, Bremen, Germany). This study was carried out in accordance with the Brazilian legislation and was approved by the Institutional Ethics Review Board of the Hospital de Clínicas, Universidade Federal do Paraná (IRB#: 2656.263/2011-11). Our study involved only bacterial isolates and no human specimens were analyzed or stored. Further, we used no patient information other than the anatomical sites from where the isolates were collected. Therefore, the same Ethics Review Board exempted us from obtaining informed consent forms.

Resistance Profile Analysis

Antimicrobial Susceptibility Testing

Isolates were tested by agar dilution against 15 antibiotics according to the Clinical and Laboratory Standard Institute guidelines (CLSI, 2015a). Minimal inhibitory concentration (MIC) was interpreted as recommended by CLSI standards

(CLSI, 2015b). Polymyxin, tigecycline and fosfomycin breakpoints were interpreted using EUCAST standards (Eucast, 2016). Modified Hodge test (MHT), double-disk synergy and hydrolysis assay were performed to determine the carbapenem resistance phenotypes, as previously described (Carvalhaes et al., 2010; Eucast, 2013).

Molecular Typing and Detection of Resistance Markers

The genetic relatedness of the *E. aerogenes* isolates were determined by pulsed-field gel electrophoresis (PFGE), as described elsewhere (Kaufmann, 1998). DNA fingerprints were interpreted as recommended by Tenover et al. (1995). The presence of the *blaMOX*, *blaCMY*, *blaLAT*, *blaBIL*, *blaDHA*, *blaACC*, *blaMIR*, *blaACT*, *blaFOX*, *blaTEM*, *blaSHV*, *blaCTX-M1*, -M2, -M8, -M9, -M25, *blaKPC*, *blaGES*, *blaIMP*, *blaVIM*, *blaNDM*, *blaSPM*, *blaGIM*, *blaSIM*, *blaOXA-23*, -48, -51, -58, and -143 was tested by PCR as previously described (Payne and Thomson, 1998; Poirel et al., 2000, 2011; Perez-Perez and Hanson, 2002; Naas et al., 2008; Higgins et al., 2009; Woodford, 2010; Nordmann et al., 2011).

Genome Sequencing, Assembly, and Annotation

Genomic DNA was extracted using DNeasy 96 Blood & Tissue Kit (QIAGEN Silicon Valley, Redwood City, USA). DNA quality was assessed using a Bioanalyzer 2100 system (Agilent Technologies, Santa Clara, USA). DNA quantification was performed using Qubit (Thermo Fisher Scientific Inc., Waltham, USA). Illumina sequencing libraries with an average fragment size of 550 bp were prepared using Illumina TruSeq DNA PCR-free LT Kit (Illumina Inc., San Diego, USA). Whole-genome sequencing of paired-end (PE) libraries was performed using a HiSeq 2500 instrument in RAPID run mode (Illumina Inc., San Diego, USA) at the Life Sciences Core Facilities of the State University of Campinas (São Paulo, Brazil). Quality-based trimming and filtering was performed using Trimmomatic version 0.32 (Bolger et al., 2014). PE reads were assembled *de novo* using Velvet version 1.2.10 (Zerbino and Birney, 2008) and contigs were scaffolded using SSPACE version 3.0 (Boetzer et al., 2011). Gene predictions and annotations were performed using NCBI Prokaryotic Genome Automatic Annotation Pipeline (PGAAP; Angiuoli et al., 2008).

Identification of Antibiotic Resistance Genes

Antibiotic resistance-related genes were predicted using the ResFinder database version 2.1 (Zankari et al., 2012) with the following parameters: “all databases” were used for antimicrobial configuration, type of reads as “assembled genomes/contigs” and thresholds of 98 identity and 80% coverage between sequences. This dataset of resistance genes was complemented with BLASTp searches against the ARDB (Antibiotic Resistance Genes Database) version 1.1 (Liu and Pop, 2009) using “resistance gene complete” database, 40% identity and e-value of 0.0001.

RESULTS

Resistance Profiles

All isolates showed MDR profile and had increased MIC for at least one carbapenem. Information regarding collection date and site, clinical setting, PFGE profile and antimicrobial resistance profiles of each isolate are available in **Table 1**. Among the four analyzed samples, C10 and D2 were isolated from different body sites of the same patient within a short period of time (a month) and belong to the same PFGE profile. These genomes allow one to analyze the possible genome plasticity between the isolates. D3 and E9 samples were isolated from two patients with an interval of collection date greater than 5 years. D3 and E9 were also interesting because of their sensitivity to meropenem

and resistance to ertapenem and imipenem. Surprisingly, E9 showed resistance to carbapenems but not to 3rd (ceftazidime and cefotaxime) and 4th generation (cefepime) cephalosporins (**Table 1**). All isolates possessed *bla*_{AmpC} and *bla*_{TEM}, as detected by PCR. The gene *bla*_{CTX-M2} was found in all isolates except E9. Phenotypic tests (i.e., Modified Hodge test and double-disk synergy) to detect carbapenemases were positive for C10, D2, and E9. However, no class A, B, and D carbapenemase encoding genes were detected by PCR. All isolates tested negative in carbapenem hydrolysis assays.

Genomic Features

We obtained between 16,841,714 and 25,138,390 150 bp PE reads per library. After genome assembly, 5,833,521 bp were assembled

in 58 scaffolds for C10, 5,821,782 bp were assembled in 57 scaffolds for D2, 5,584,745 bp were assembled in 55 scaffolds for D3 and 5,637,471 bp were assembled in 59 scaffolds for E9. By using the NCBI Prokaryotic Annotation Pipeline, we were able to predict 5,363, 5,380, 5,067, and 5,129 protein-coding sequences in each of the genomes listed above, respectively. Genomic features of the four sequenced genomes are summarized in **Table 1**.

Antibiotic Resistance Genes

A total of 18 enzymes related to antibiotic resistance were identified using ResFinder, ARDB and PGAAP (**Table 2**). All isolates harbor genes related to: (i) aminoglycoside resistance (genes *aacA4* and *aadA*); (ii) beta-lactam resistance, including genes belonging to class A beta-lactamases (TEM family), class B beta-lactamases (Ribonuclease Z), class C beta-lactamases (CMY/LAT/MOX/ACT/MIR/FOX family) and class D beta-lactamases (OXA-9); (iii) bacitracin resistance (gene *bacA*), and (iv) sulphonamide resistance (gene *sul1*; **Table 2**). Genes *sul2* and *rmtD* were only identified in *E. aerogenes* D3. The gene *sul2* has been implicated on sulphonamide resistance for inducing high expression levels of the enzyme dihydropteroate synthase (Sköld, 2001), while *rmtD* has been related to aminoglycoside resistance and this variant was identified for the first time in South America in a *P. aeruginosa* isolate in 2005 (Doi et al., 2007). Interestingly, *E. aerogenes* D3 was isolated in 2006, indicating that this variant has spread amongst *Enterobacteriaceae* in Brazil since its first report (Doi et al., 2007).

Although the four isolates showed carbapenem-resistance, no carbapenemase gene was identified using molecular detection or *in silico* analysis. Hence, it is likely that these isolates employ alternative mechanisms to counter carbapenem effects. Various multidrug efflux transporters were found in the genomes described here (**Table 2**). They belong to four superfamilies: the major facilitator superfamily (MFS), multidrug and toxic compound extrusion (MATE), ATP-binding cassette (ABC) and resistance-nodulation-cell division (RND). RND type of transporters has been often associated with multidrug resistance of Gram-negative bacteria (Nikaido, 1998). In particular, the RND type genes forming the AcrA-AcrB-TolC efflux pump were found in multiple copies in our isolates (**Table 2**). Experimental evolution studies of *E. aerogenes* under successive imipenem exposure reported alterations in membrane permeability with complete loss of porins (e.g., Omp35 and Omp36) and overexpression of AcrAB-TolC efflux pumps (Bornet et al., 2003; Thiolas et al., 2005; Lavigne et al., 2012). As a result of efflux pump expression, the *E. aerogenes* isolates showed resistance to carbapenems and other antibiotics, especially fluoroquinolones (Bornet et al., 2003; Thiolas et al., 2005; Lavigne et al., 2012). Given the multiple copies of genes encoding efflux pumps in our isolates, it is possible that an increased expression of AcrAB-TolC efflux pumps could contribute to the observed carbapenem-resistant profiles.

E. aerogenes is an emergent nosocomial pathogen with a diversity of mechanisms to circumvent antimicrobial activity. Here we reported the phenotypic screens, genome sequencing, and prediction of putative resistance gene repertoires of four multidrug-resistant *E. aerogenes* isolated between 2006 and 2012.

The data reported here may help understand the biochemistry, evolution, and epidemiology of this important pathogen. The material provided in this work may be used in future comparative genomics and molecular epidemiology studies aiming to clarify the resistance profiles and dynamics of multidrug-resistant *Enterobacteriaceae* species.

DATA ACCESS

The genome sequence of *E. aerogenes* C10, *E. aerogenes* D2, *E. aerogenes* D3 and *E. aerogenes* E9 have been deposited in DDBJ/EMBL/GenBank under the accession numbers LUTZ00000000, LSOH00000000, LUTT00000000, and LULD00000000, respectively. Data are available in FASTA, annotated GenBank flat file and ASN.1 formats. The respective genome versions described in this paper are LUTZ01000000, LSOH01000000, LUTT01000000, and LULD01000000. Sequencing reads (fastq format) of each isolate were deposited in Sequence Read Archive (SRA) under the accession numbers SRP083774 (*E. aerogenes* C10), SRP083784 (*E. aerogenes* D2), SRP083785 (*E. aerogenes* D3), and SRP083786 (*E. aerogenes* E9). Users can download the data for research purposes, citing the present manuscript as original reference.

AUTHOR CONTRIBUTIONS

AG, NV, JP, LD, and TV conceived the idea and designed the study. JP performed the sample collections and wet lab experiments. AG and NV carried out the genome analysis. AG, NV, JP, LD, and TV interpreted the data and wrote the manuscript. All authors have read and approved the final version of this manuscript.

ACKNOWLEDGMENTS

This work was supported by Fundação Carlos Chagas Filho de Amparo à Pesquisa do Estado do Rio de Janeiro (FAPERJ; E-26/110.236/2011 and E-26/102.259/2013). This research was partially supported by the Intramural Research Program of the National Library of Medicine (NLM), National Institutes of Health (NIH). NV postdoctoral fellowship is funded by a partnership between CNPq and NIH. TV is a recipient of an established investigator fellowship award from Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq). We thank Bruker Corporation of Brazil for performing the MALDI-TOF assay and the staff of the Life Sciences Core Facility (LaCTAD), from State University of Campinas (UNICAMP), for library preparation and genome sequencing.
