Background: Accumulating evidence has implicated DNA methylation in the progression of atherosclerosis (AS). Rnase6 has been reported to be upregulated in AS development, but the specific regulatory mechanism remains unclear.

Material/Methods: Peripheral blood and sclerotic plaque tissues from 25 AS patients were collected to detect Rnase6 expression. Methylation-specific polymerase chain reaction (MSP) was used to detect Rnase6 methylation levels in the peripheral blood of AS patients. Rnase6 expression was knocked down or DNA methyltransferase 1 (DNMT1) was overexpressed in OX-LDL-treated mouse aortic smooth muscle cells (MOVAS), and cell proliferation, migration, ROS content, and inflammatory factor secretion levels were detected. 740 Y-P, a PI3K specific agonist, was introduced to verify the effect of Rnase6 promoter hypomethylation on the PI3K/Akt signaling pathway. We knocked down Rnase6 expression in ApoE^{-/-} mice fed with a high-fat diet to examine Rnase6 promoter methylation levels. Plaque areas and inflammatory factor secretion were examined in AS mice overexpressing DNMT1.

Results: Rnase6 expression was upregulated in the peripheral blood and plaque tissues of AS patients, accompanied by decreased methylation levels of the Rnase6 promoter. Interfering with Rnase6 expression or overexpressing DNMT1 in OX-LDL stimulated MOVAS inhibited cell proliferation and migration, decreased ROS content and inflammatory factor secretion, and inhibited PI3K pathway protein expression. Rnase6 expression was decreased in the peripheral blood and plaque tissues of si-Rnase6-injected mice, and Rnase6 promoter methylation was increased. Mice overexpressing

Abbreviations: AS, atherosclerosis; ECs, endothelial cells; VSMCs, vascular smooth muscle cells; DNMT1, DNA methyltransferase 1; Rnase6, Ribonuclease 6; RNaseA, Ribonuclease A; MOVAS, mouse aortic vascular smooth muscle cells; OX-LDL, low-density lipoprotein; MSP, methylation-specific polymerase chain reaction; ApoE, apolipoprotein E; PI3K, phosphoinositide 3 kinase; SDS-PAGE, sodium dodecyl sulfate polyacrylamide gel electrophoresis; PVDF, polyvinylidene difluoride; HRP, horseradish peroxidase.

DNMT1 showed less plaque areas in the aortic root and lower secretion levels of inflammatory factors.

Conclusion: Hypomethylation of the promoter of Rnase6 enhanced the proliferation and migration of OX-LDL treated MOVAS, upregulated ROS content and inflammatory factor secretion levels in the cells, and activated the PI3K/Akt signaling pathway.

Keywords: atherosclerosis, ribonuclease 6, hypomethylation, murine aortic vascular smooth muscle cells, proliferation, migration

INTRODUCTION

Atherosclerosis (AS) is a chronic inflammatory disease caused by multiple factors. It is characterized by vascular endothelial dysfunction, subintimal lipid deposition, abnormal migration and proliferation of smooth muscle cells, and foam cell formation. It can involve the arterial blood vessels of important organs of the whole body, in which a variety of vascular cells such as endothelial cells, smooth muscle cells, macrophages and lymphocytes are involved in the occurrence of AS (Lacey et al., 2019; Gao, et al., 2019; Sun, et al., 2019). Studies have shown that dysfunction of endothelial cells (ECs) leading to the deposition of cholesterol and other lipids in the vessel wall is the initial event leading to the occurrence of AS (Viafara-Garcia, et al., 2018; Deng, et al., 2018). Damage to ECs also leads to the invasion of proinflammatory factors into the intima and abnormal proliferation of vascular smooth muscle cells (VSMCs) (Baumer, et al., 2017; Li, et al., 2017; Yu, et al., 2018). During the progression of AS, VSMCs undergo dedifferentiation, proliferation, migration under stress conditions, and promote fibrous cap formation. VSMCs can transform into macrophage like cells that are proinflammatory and dysfunctional and “synthetic” smooth muscle cells that can produce extracellular matrix, increasing the risk of myocardial infarction.

Increasing evidence indicates that epigenetics, such as DNA methylation, acetylation, glycosylation and phosphorylation, play an important role in the occurrence and development of many diseases and regulate gene expression (Abdel-Hafiz and Horwitz, 2015; Wu, et al., 2020). Among them, DNA methylation refers to the methyl group in S-adenosylmethionine is transferred to cytosine by DNA methyltransferase (DNMT) to form 5-methylcytosine, which is methylated (Guarrera, et al., 2019; Jamebozorgi, et al., 2018). DNA methylation in humans and mammals is mainly associated with CpG dinucleotides, and hypermethylation of CpG islands in the promoter region can inhibit gene expression. In recent years, a large number of studies have shown that DNA methylation and other factors are involved in the regulation mechanism of atherosclerosis. Wei et al. found that SMAD7 expression was decreased and its promoter region was significantly methylated in atherosclerotic plaques compared with normal arterial walls. And increased DNA methylation levels of the SMAD7 promoter at CpG unit 5.8.15.16 were found in the peripheral blood of patients with atherosclerosis compared with normal controls, suggesting that methylated SMAD7 may be a novel predictive marker for atherosclerosis (Wei, et al., 2018). In addition, Xia et al. identified 174

upregulated genes with hypomethylation in the promoter and 86 downregulated genes with hypermethylation in the promoter in as vs. healthy controls, found that signaling lymphocyte activation molecule 7 (SLAMF7) was expressed at high levels in carotid plaques, and the expression of SLAMF7 protein was significantly higher in unstable plaques than in stable plaques (Xia, et al., 2018).

Recently, researchers performed comprehensive bioinformatics analysis on specimens from 16 advanced plaques and 13 early plaques, identified differentially expressed genes, and obtained protein-protein interaction networks. Among them, Ribonuclease 6 (Rnase6) was reported to occur in AS with up-regulated expression (Zhao, et al., 2020). Rnase6 belongs to the secreted protein of the Ribonuclease A (RNaseA) superfamily and has a wide range of physiological functions, including digestion, cytotoxicity, angiogenesis, male reproduction and host defense (Lang, et al., 2019). It has been reported that Rnase6 shows higher expression in uterine tissues with abnormal placental expulsion after delivery, leading to macrophage polarization toward M2 phenotype and aggravating the inflammatory process during placental expulsion (Nelli, et al., 2019). However, the specific regulatory mechanism of Rnase6 in the process of atherosclerosis is still unclear and needs further exploration.

In this study, we used promoter methylation of Rnase6 as an entry point to explore the specific regulatory mechanisms of decreased promoter methylation of Rnase6 on cell proliferation, migration, oxidative stress and inflammation in MOVAS cells treated with OX-LDL, to understand the role of Rnase6 in the development and progression of AS, and to provide a new reference for evaluating the potential therapeutic potential of Rnase6 for AS treatment.

MATERIALS AND METHODS

In this study, we examined the expression levels of Rnase6 in the peripheral blood of healthy volunteers and patients with AS, as well as in plaque tissues and surrounding healthy arteries from patients with AS. Next, MOVAS cells were treated with OX-LDL, and the levels of Rnase6 expression, cell proliferation, migration, oxidative stress, inflammatory factor secretion, and PI3K signaling pathway protein expression were examined. We predicted the presence of a CpG island at the mouse Rnase6 gene promoter by online bioinformatics databases, and ChIP experiments confirmed DNMT1 binding to Rnase6. DNMT1 was overexpressed in MOVAS cells treated with OX-LDL, and the levels of Rnase6 expression, cell proliferation, migration, oxidative stress, secretion

of inflammatory factors, and PI3K signaling pathway protein expression were examined. An ApoE knockout mouse model with knockdown of Rnase6 expression was constructed, and the Rnase6 expression and methylation levels in mouse peripheral blood were detected. An ApoE knockout mouse model overexpressing DNMT1 was constructed to determine the expression levels of Rnase6 and inflammatory factors in aortic root tissues, and the plaque areas in aortic root were observed by HE staining.

Samples

Atherosclerotic plaque tissue specimens and adjacent healthy arterial wall specimens were obtained from patients undergoing carotid endarterectomy ($n = 25$, 69.35 ± 4.2 years). And 10 ml of peripheral venous blood of patients was collected for the study the day before surgical treatment. In addition, atherosclerotic plaques and healthy arteries were obtained from patients undergoing carotid endarterectomy. The collected samples were washed in precooled PBS (0.02 mol/L, pH 7.0–7.2) to remove blood and added to 5 ml PBS for thorough grinding. The prepared homogenates were homogenized in $5,000 \times g$ centrifuged for 5 min, and the supernatant was retained and used for subsequent studies. The study protocol was approved by the Ethics Committee of Xi'an Central Hospital, followed the Declaration of Helsinki and other bioethical principles, and obtained written informed consent from each participant.

Cell Culture

Mouse aortic vascular smooth muscle cells were purchased from the American Type Culture Collection (ATCC, Manassas, VA, United States). Cells were incubated with 10% fetal bovine serum and 100 U/mL penicillin and 100 μ g/ml streptomycin (Sigma, St. Louis, MO, United States) in RPMI 1640 medium (Gibco, Rockville, MD) containing 5% CO₂. Small interfering RNA (si-Rnase6, 30 nM) and negative control of Rnase6 (scramble) were purchased from Santa Cruz Biotechnology (Santa Cruz, CA, United States). The siRNA sequences were as follows: for sense Rnase6 siRNA: 5'-GGA GCU AGC UGU UAG CUA AUU-3', for antisense Rnase6 siRNA: 5'-UUA GCU AAC AGC UAG CUC CCA-3'; for control siRNA (scramble): 5-UUC UCC GAA CGU GUC ACG UTT-3. The overexpression plasmid of DNMT1 (pcDNA-DNMT1, 2 μ g/ml) was purchased from RiboBio Co., Ltd. (Guangzhou, China). All reagents were transfected into cells using Lipofectamine 3,000 transfection reagent (Invitrogen, Carlsbad, CA, United States) according to the manufacturer's instructions. In addition, OX-LDL treatment of mouse aortic vascular smooth muscle cells for 48 h induced foam cell formation.

Animals

Eight-week-old C57BL/6 pure line ApoE gene knockout (ApoE^{-/-}) mice were purchased from Guangdong Animal Experimental Center. The ratio of male to female was 1:1, and all animals were housed in separate cages in temperature and light cycle-controlled environments with free access to food and water. Sixteen ApoE^{-/-} mice were divided into control group (ApoE^{-/-} mice were given a basal diet), model group (ApoE^{-/-} mice were given a high-fat diet), scramble group (scramble was injected into the tail vein of high fat diet fed ApoE^{-/-} mice, 0.5 mg/kg, twice a

week) and si-Rnase6 group (si-Rnase6 was injected into the tail vein of high fat diet fed ApoE^{-/-} mice, 0.5 mg/kg, twice a week), with four mice in each group. Besides, eight ApoE^{-/-} mice were divided into pcDNA3.1 group (pcDNA3.1 was injected into the tail vein of high fat diet fed ApoE^{-/-} mice, 200 μ g/ml) and pcDNA-DNMT1 group (pcDNA-DNMT1 was injected into the tail vein of high fat diet fed ApoE^{-/-} mice, 200 μ g/ml), with four mice in each group. High-fat diet feeding protocol: mice were fed with a diet containing 1.25% cholesterol, 0.5% cholic acid, and 15% fat for 10 weeks. All animal care and experimental procedures were approved by the Ethics Committee of Xi'an Central Hospital.

CCK-8 Assay

The murine aortic vascular smooth muscle cells cultured for the indicated periods of time (0–72 h), and cell viability was detected using the Cell Counting Kit-8 (CCK-8) according to the manufacturer's instructions (Beyotime Institute of Biotechnology, Shanghai, China) and read using a microplate reader (Synergy HT, BioTek), at 450 nm.

ELISA

The secretion level of Rnase6 in peripheral blood of atherosclerotic patients and mice was determined by ELISA kits (Sigma, St. Louis, MO, United States) according to the manufacturer's instructions. Similarly, the secretion levels of TNF- α , IL-6 and IL-1 β in cell culture supernatants were also detected by ELISA kits.

ROS Content Detection

MOVAS were plated at 1.5×10^5 density seeded in culture flasks. MOVAS without any treatment were used as the control group. MOVAS were treated with OX-LDL (80 μ g/ml) alone for 24 h, or transfected together with si-Rnase6 for 48 h. ROS kit (S0033, Beyotime, Shanghai, China) was used to measure ROS levels according to the manufacturer's instructions. Dichloro-dihydro-fluorescein diacetate (DCFH-DA; 10 μ M) was added to the cells and incubated for 20 min at 37°C. The cells were then digested and suspended. The cell suspensions were centrifuged at $1,000 \times g$ for 10 min and washed twice with phosphate-buffered saline (PBS). The cells were collected after centrifugation for fluorescence detection. Flow cytometry was used to measure fluorescence intensity. The positive area of DCFH-DA was ROS fluorescence intensity.

Chromatin Immunoprecipitation

EZ-Magna ChIP TMA kit (Millipore, Billerica, MA) were employed for chromatin immunoprecipitation (ChIP) analysis following the manufacturer's guideline. Briefly, MOVAS were cross-linked with 1% formaldehyde for 10 min, and then 125 mM glycine was added to terminate the crosslinking. Next, cells were lysed in lysis buffer, and chromatin fragments at 200–1,000 bp were obtained by cracking the cells through ultrasound. The supernatant was centrifuged and the fragments were collected in three tubes, which were supplemented with the target protein specific antibody (DNMT1, ab13537, Abcam) or the negative control antibody (IgG, ab10948, Abcam) for incubation at 4°C overnight. The DNA-protein complex was precipitated with

Protein Agarose/Sepharose. The precipitated DNA fragments were purified and subjected to RT-qPCR analysis.

Western Blotting

Protein homogenates from cells were extracted. The specific operation was as follows: the cells were collected and rinsed with PBS for 2 times, and 10 ml culture solution was added after trypsinization to prepare a cell suspension. The cell suspension was moved into a centrifuge tube at 4°C, 2,500 rpm, and the supernatant was discarded after centrifugation for 5 min, repeated twice. Then 200 µl cell lysate was added to the cell suspension and lysed for 40 min, and the supernatant was collected by centrifugation at 12,000 rpm for 5 min at 4°C. The protein content (40 µg) of each sample was determined by using the BCA Protein Assay Kits (Thermo Scientific). Then, equal amounts of protein (12 µg/lane) were separated on 12% sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to polyvinylidene fluoride (PVDF) membranes (Bio-Rad, Hercules, CA, United States). The membranes were blocked in 5% (w/v) skimmed milk powder in TBST (Tris buffered saline-0.1% Tween) for 2 h at 25°C, and then incubated with the following antibodies: rabbit polyclonal anti-β-actin antibody (1:1,000, Abcam, ab8227), rabbit monoclonal anti-PI3K antibody (1:1,000, Abcam, ab32089), rabbit polyclonal anti-AKT antibody (1:500, Abcam, ab8805), rabbit polyclonal anti-AKT (phospho T308) antibody (1:600, Abcam, ab38449), rabbit monoclonal anti-mTOR antibody (1:10,000, Abcam, ab134903), rabbit monoclonal anti-mTOR (phospho S2448) antibody (1:6,000, Abcam, ab109268), rabbit monoclonal anti-DNMT1 antibody (1:1,000, Abcam, ab188453). Before the ECL protocol (Amersham Biosciences, Piscataway, NJ, United States), the bands were visualized using horseradish peroxidase (HRP)-conjugated goat anti-rabbit IgG (1:5,000, Abcam, ab6721).

Methylation-Specific Polymerase Chain Reaction

The methylation degree of Rnase6 gene promoter in peripheral blood from atherosclerotic patients or mice was determined by MSP. Conditions for polymerase chain reaction with Bisulfite-modified DNA: 95°C for 5 min, followed by 35 cycles of 95°C for 30 s, 64°C for 30 s, and 72°C for 30 s, with a final extension of 60°C for 30 min. Methylated (M) and unmethylated (U) PCR products were detected by gel electrophoresis. The relative intensity of bands was quantified with ImageJ (National Institutes of Health, Bethesda, MD, United States). The MSP primer sequences were shown below: Rnase6-MSP-M-F1 5'-TGG TTA AAT TTT AGA GGT CGG-3'; Rnase6-MSP-M-R1 5'-CGA TTA TAA ACT CAT AAC TAA AAA CGA AA-3'; Rnase6-MSP-U-F1 5'-GGT TAA ATT TTA GAG GTT GG-3'; Rnase6-MSP-U-R1 5'-TTA ACA ATT ATA AAC TCA TAA CT AAA AAC A-3'.

Statistical Analysis

All statistical analyses were performed by using the SPSS software (ver. 17.0; SPSS, Chicago, IL). The quantitative data derived from three independent experiments are expressed as mean ± standard error of mean (SEM). The Shapiro-Wilk test was used to verify that the data fit a normal distribution. Levene's test was used to

test for homogeneity of variance. A one-way analysis of variance (ANOVA) or Kruskal-Wallis non-parametric test was employed according to normal distribution and homogeneity of variance. The Kruskal Wallis test and post hoc analysis (Mann-Whitney *U* test) were used to assess pairwise differences between adjusted means. Values of $p < 0.05$ were considered statistically significant.

RESULTS

Result 1 Upregulated Expression of Rnase6 in Peripheral Blood and Plaque Tissues of Atherosclerotic Patients

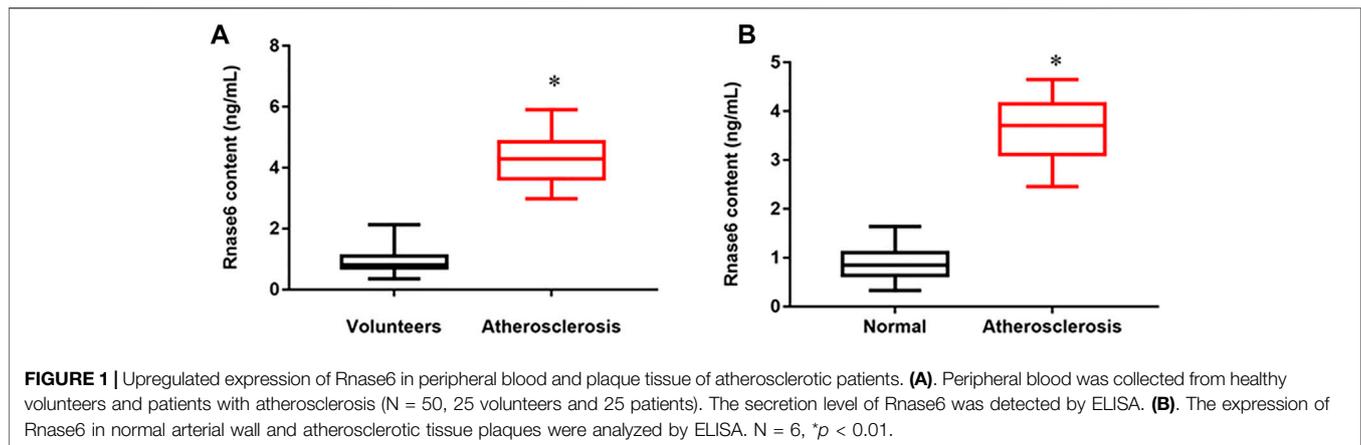

We collected peripheral blood from healthy volunteers and patients with atherosclerosis, and the results of ELISA showed that the expression of Rnase6 was significantly up-regulated in the peripheral blood of patients (Figure 1A). In addition, we obtained atherosclerotic plaque tissue and healthy arteries from patients undergoing carotid endarterectomy, and ELISA results suggested that Rnase6 expression in plaque tissue was also significantly increased (Figure 1B). The characteristics of subjects included in this study was shown in Table 1.

Result 2 Interference With Rnase6 Expression Inhibited OX-LDL-Induced Proliferation and Migration of MOVAS Cells

Our previous results showed that the expression of Rnase6 was up-regulated in the peripheral blood and plaque tissues of atherosclerotic patients. To study the regulatory role of Rnase6 in the development of AS more clearly, OX-LDL was used to induce mouse aortic vascular smooth muscle cells (MOVAS), and small interfering RNA of Rnase6 (si-Rnase6) was transfected into the cells. ELISA results showed that OX-LDL-induced upregulation of Rnase6 expression in MOVAS cells (Figure 2A), enhanced cell proliferation (Figure 2B) and migration (Figures 2C,D), increased reactive oxygen species (ROS) content (Figure 2E), and increased secretion of proinflammatory factors (Figure 2F), accompanied by increased phosphorylation levels of PI3K, AKT and mTOR proteins (Figures 2G,H). Conversely, interfering with Rnase6 expression significantly reversed the changes in cell behavior induced by OX-LDL.

Result 3 The Presence of CpG Islands in the Promoter Region of Rnase6

In the progression of atherosclerosis, it may be accompanied by epigenetic changes of genes, leading to overexpression or significant inhibition of genes. Therefore, we continue to explore the mechanism of up-regulation of Rnase6 expression. We predicted CpG islands in the promoter region of the Rnase6 gene through an online biological database (<http://www.urogene.org/methprimer2/>) and found that there were indeed CpG islands upstream of its transcription start site (5,000 bp) (Figure 3A). Next, methylation-specific polymerase chain reaction (MSP) was used to detect the methylation status of Rnase6 in peripheral blood of healthy volunteers and patients with atherosclerosis. The results suggested

that the Rnase6 gene was hypermethylated in the peripheral blood of healthy volunteers and hypomethylated in the peripheral blood of patients, which further confirmed that the up-regulation of Rnase6 expression was closely related to its decreased methylation level (Figure 3B). As the core enzyme catalyzing DNA methylation, DNA methyltransferase 1 (DNMT1) plays an important role in the methylation of CpG islands. ChIP results showed that was DNMT1 enriched in the promoter region of Rnase6 (Figure 3C).

Result 4 Promoting Rnase6 Promoter Methylation Inhibited OX-LDL-Induced Proliferation and Migration of MOVAS Cells

We previously verified that DNMT1 could bind to Rnase6, suggesting that overexpression of DNMT1 in OX-LDL-induced MOVAS cells may affect Rnase6 promoter

methylation and regulate its expression. As expected, transfection of pcDNA-DNMT1 significantly inhibited OX-LDL-induced Rnase6 expression in MOVAS cells (Figure 4A), decreased DNMT1 protein expression (Figure 4B), attenuated cell proliferation (Figure 4C) and migration (Figures 4D,E). Furthermore, ROS content (Figure 4F) and secretion level of proinflammatory factors (Figure 4G) in cells were also significantly reduced after overexpression of DNMT1. Western blotting results suggested that OX-LDL induction promoted the phosphorylation of PI3K signaling pathway-related proteins in cells, while transfection of pcDNA-DNMT1 reversed the expression level of phosphorylated proteins in cells (Figures 4H,I).

Result 5 Hypomethylation of Rnase6 Promoter Activated PI3K/AKT/mTOR Signaling Pathway

Our previous results showed that overexpression of DNMT1 significantly reduced the expression of phosphorylated proteins in OX-LDL-induced MOVAS cells. Here, we introduced 740 Y-P, a PI3K agonist, to further validated the regulation of PI3K signal transduction system by hypomethylation of Rnase6 promoter. Western blotting results showed that 740 Y-P reversed the inhibitory effect of overexpressing DNMT1 on PI3K signaling pathway-related protein expression (Figures 5A,B). Moreover, the intervention of 740 Y-P re-enhanced the ability of cell proliferation (Figure 5C) and migration (Figure 5D,E), reduced ROS content (Figure 5F), and inhibited the secretion of proinflammatory factors (Figure 5G).

Result 6 Hypomethylation of Rnase6 Promoter Aggravated Atherosclerosis in Mice

We interfered with Rnase6 expression in apolipoprotein E (ApoE) knockout mice fed a high-fat diet and then collected peripheral blood and atherosclerotic plaques. ELISA results showed that the expression level of Rnase6 in peripheral blood and atherosclerotic plaques of atherosclerotic mice transfected

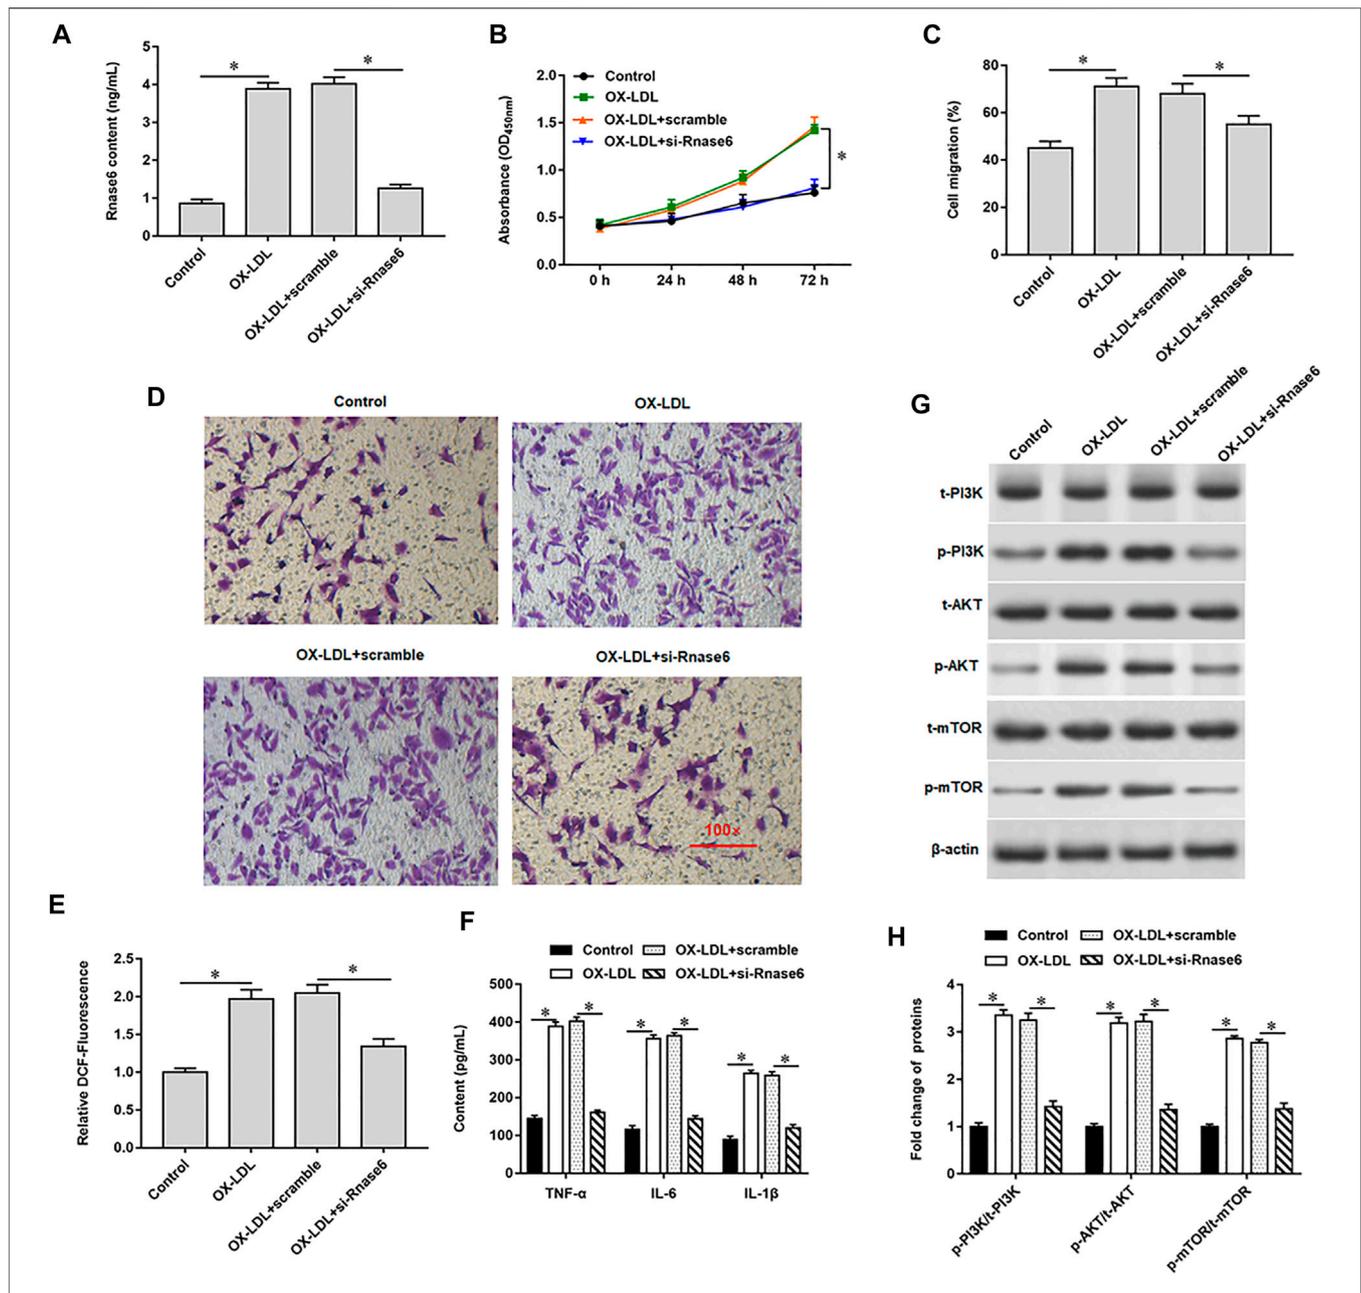

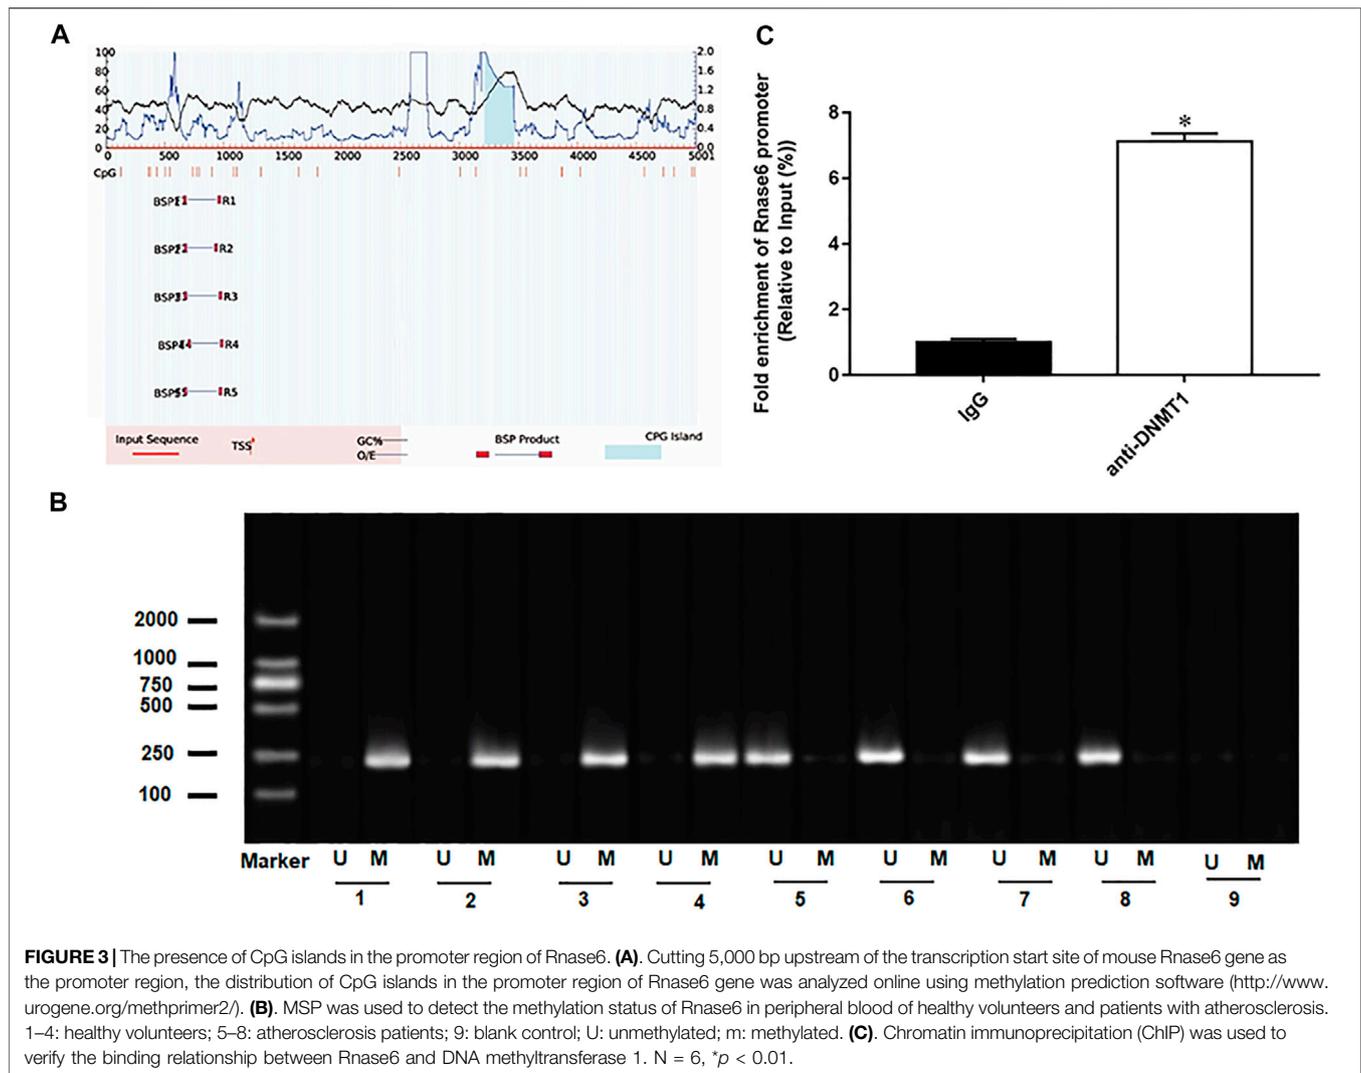

FIGURE 2 | Interference with Rnase6 expression inhibited OX-LDL-induced proliferation and migration of MOVAS cells. with si-Rnase6 was significantly down-regulated compared with model mice (**Figures 6A,B**). In addition, MSP results showed that Rnase6 promoter was hypermethylated in peripheral blood of atherosclerotic mice whose Rnase6 expression was disturbed (**Figure 6B**).

We overexpressed DNMT1 in apolipoprotein E (ApoE) knockout mice fed a high-fat diet. Western blotting results indicated increased DNMT1 expression in peripheral blood

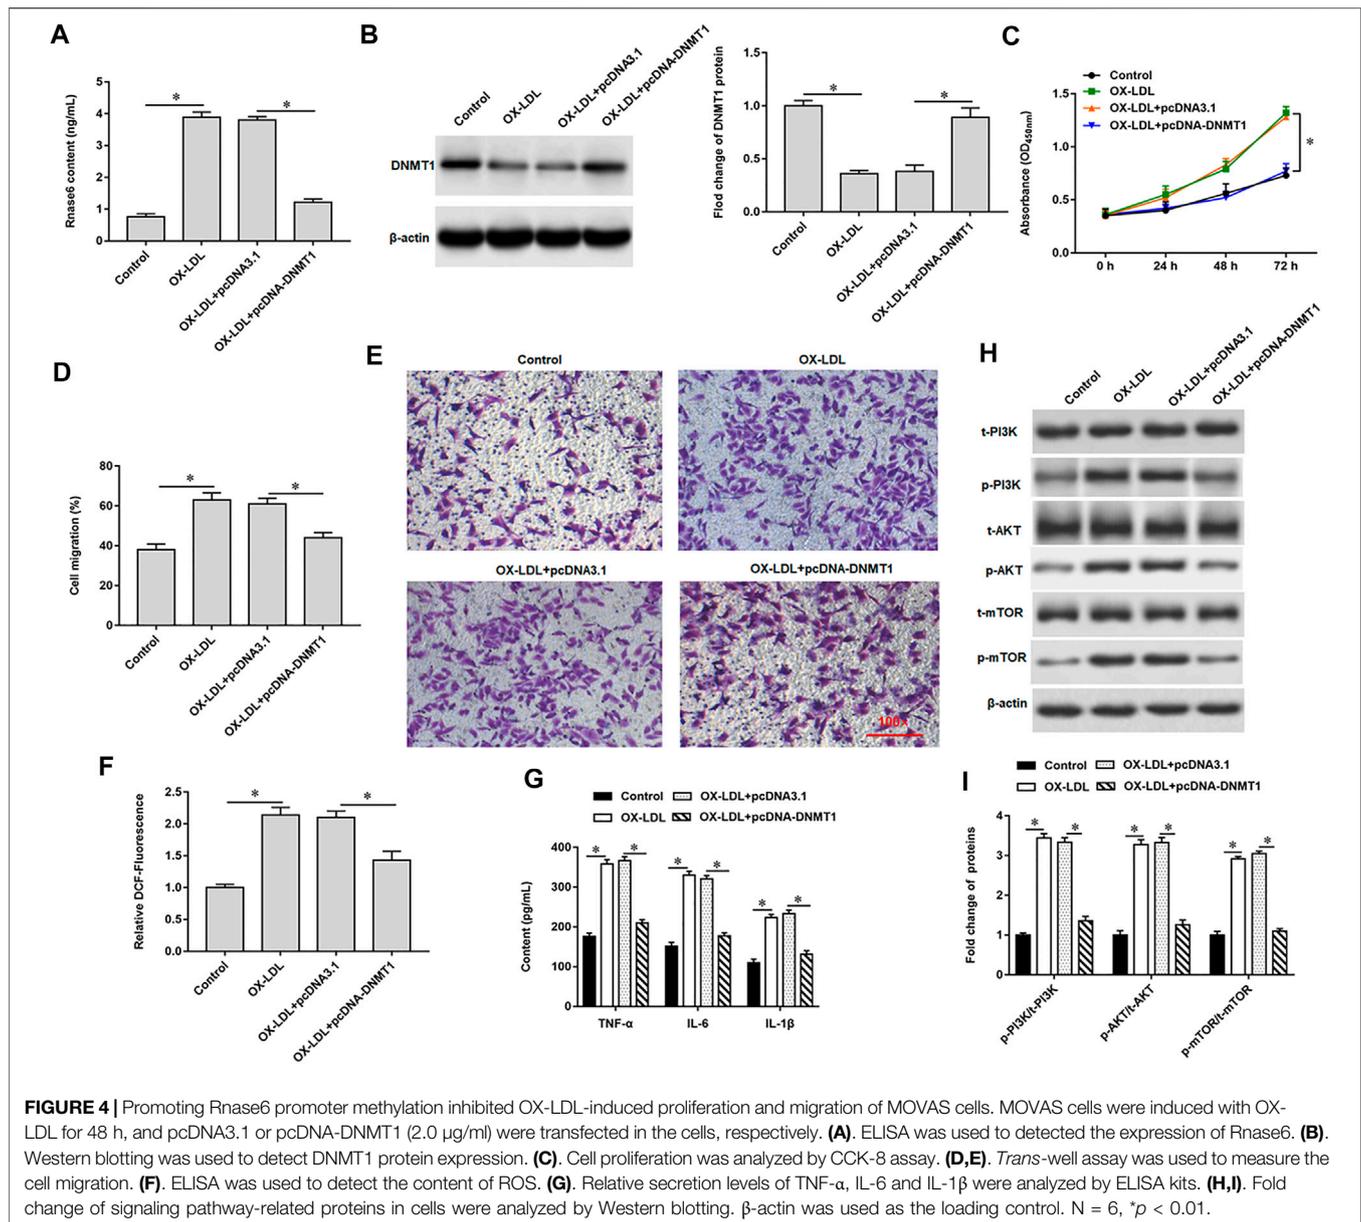

(**Figures 6D,E**) and sclerotic plaques (**Figures 6D,F**). ELISA analysis showed that Rnase6 protein expression levels were reduced in peripheral blood (**Figure 6G**). HE staining of mouse aortic root tissue revealed that overexpression of DNMT1 reduced the area of sclerotic plaque (**Figure 6H**). In addition, secretion of proinflammatory factors was reduced in the serum of atherosclerotic mice transfected with si-Rnase6 compared with model mice (**Figure 6I**).

DISCUSSION

Growing evidence suggests that epigenetic modifications play a crucial role in the regulation of gene expression, and DNA methylation occurring on CpG islands has been recognized as a universal mechanism for regulating gene expression in mammals (Heidari, et al., 2019). DNA promoter methylation has been widely reported as a novel epigenetic marker during atherosclerosis progression. Wei et al. reported that Smad7 expression was decreased in atherosclerotic plaques compared with normal arterial walls. Smad7 promoter DNA methylation levels at CpG unit 5.8.15.16 were increased in the peripheral blood of atherosclerosis patients compared with normal controls, and correlation analysis indicated that Smad7 promoter DNA methylation levels were positively correlated with homocysteine levels (Wei, L. et al., 2018). Hu et al. found that romidepsin attenuated TNF- α induced VCAM-1 expression and monocyte adhesion on the surface of HAECs by inhibiting HDAC1/2. Mechanistic studies suggested that down-regulation of VCAM-1

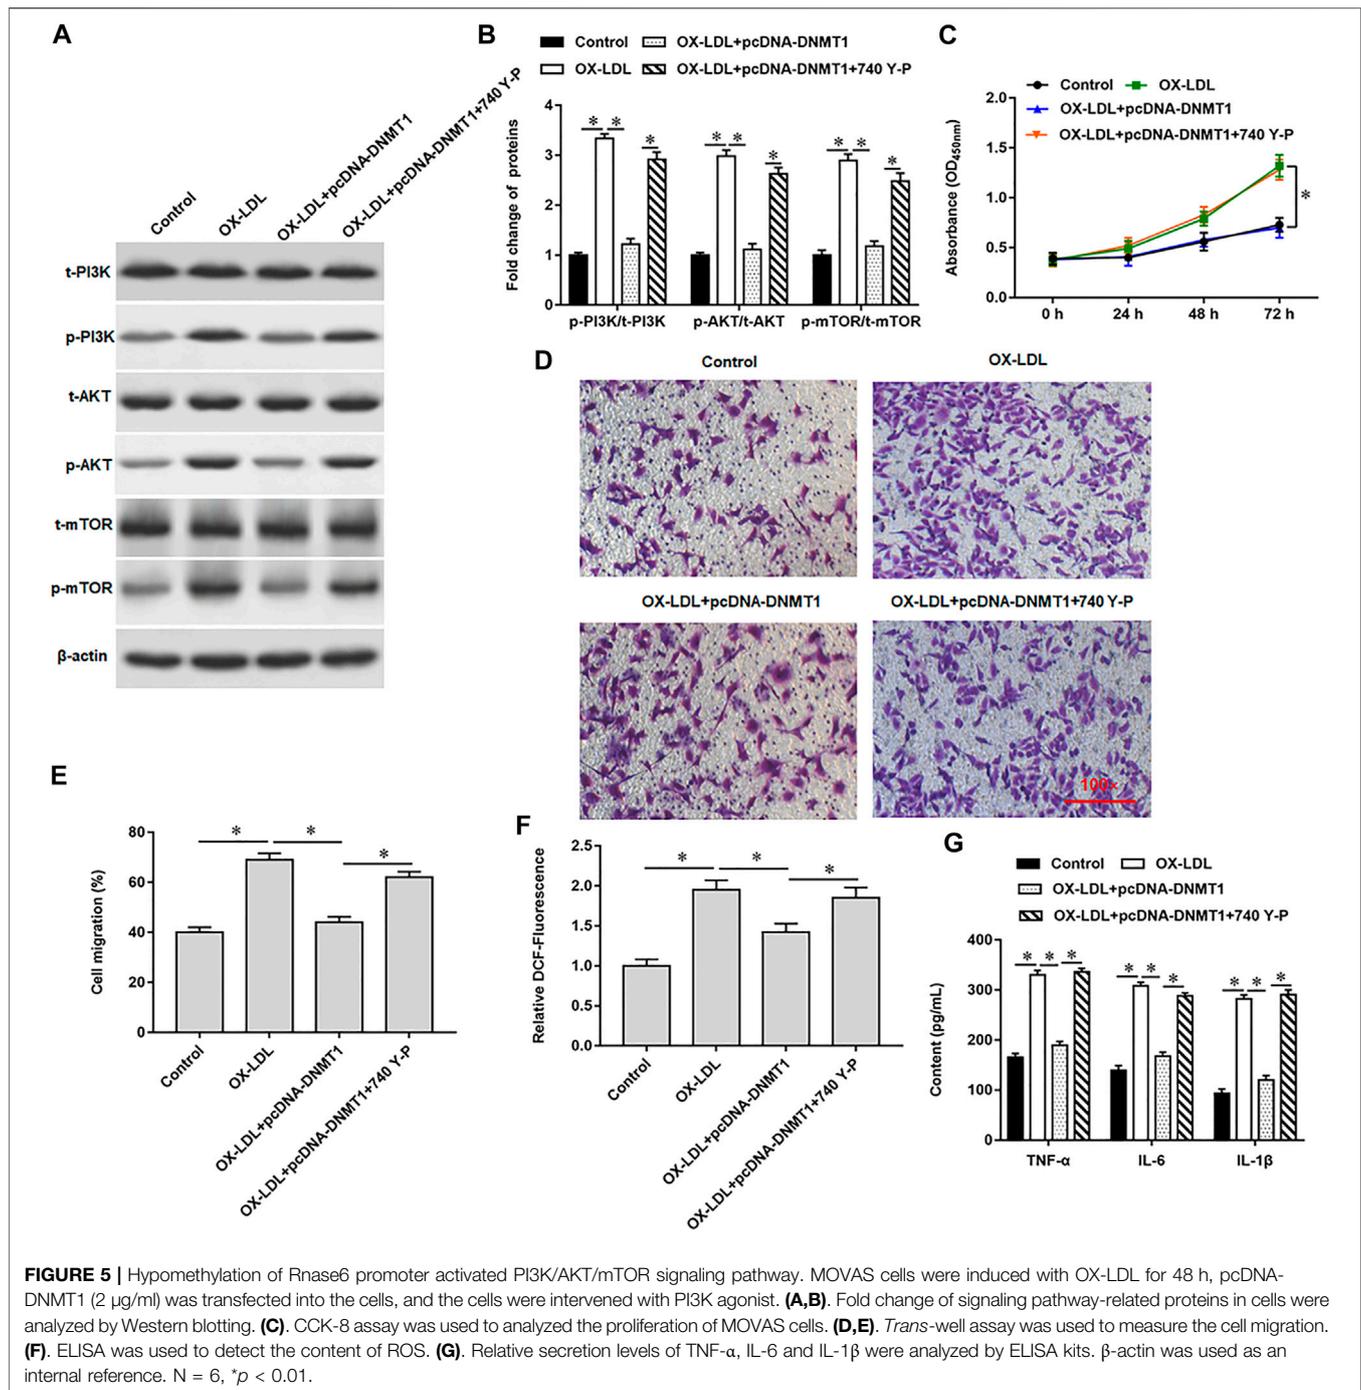

was attributed to decreased expression of the transcription factor GATA6. Romidepsin enhances STAT3 acetylation and its binding to DNMT1, leading to hypermethylation of promoter CpG rich regions at +140/+255. Blocking STAT3 acetylation at lys685 disrupts DNMT1-STAT3 interaction, decreases promoter methylation, and reverses the inhibitory effect of HDAC1/2 inhibition on GATA6 and VCAM-1 expression. These findings may provide a rationale for HDAC1/2-targeted therapy in atherosclerotic heart disease (Hu, et al., 2021). A survey of 30 patients with polycystic ovary syndrome reported that the methylation of TOX3 gene promoter in serum and granulosa cells of patients was significantly lower than that in healthy volunteers, suggesting that abnormal methylation of TOX3 gene has a significant promoting effect on the occurrence of polycystic ovary syndrome (Ning, et al., 2017). In addition, studies have shown that over expression of histone methyltransferase enhancer of Zeste homolog-2 lead to downregulation of ABCA1 gene in macrophage derived foam cells and accelerates atherosclerosis by promoting

ABCA1 promoter methylation (Lv, et al., 2016). DNA methyltransferase inhibitor 5-aza-2'-deoxycytidine (5-aza-dC) was administered to LDL receptor knockout mice fed a high-fat diet, and it was found that 5-aza-dC-treated macrophages downregulated the expression of pro-inflammatory factors, attenuated the migration and adhesion of macrophages, thereby delaying the progression of atherosclerosis (Cao, et al., 2014).

Atherosclerosis is the main pathological basis of cardiovascular and cerebrovascular diseases, and its cardiovascular and cerebrovascular events are characterized by high mortality and disability rates. Therefore, starting from the cellular and molecular biological mechanisms of AS, exploring its therapeutic targets is of great significance for seeking drugs to effectively prevent and treat atherosclerosis.

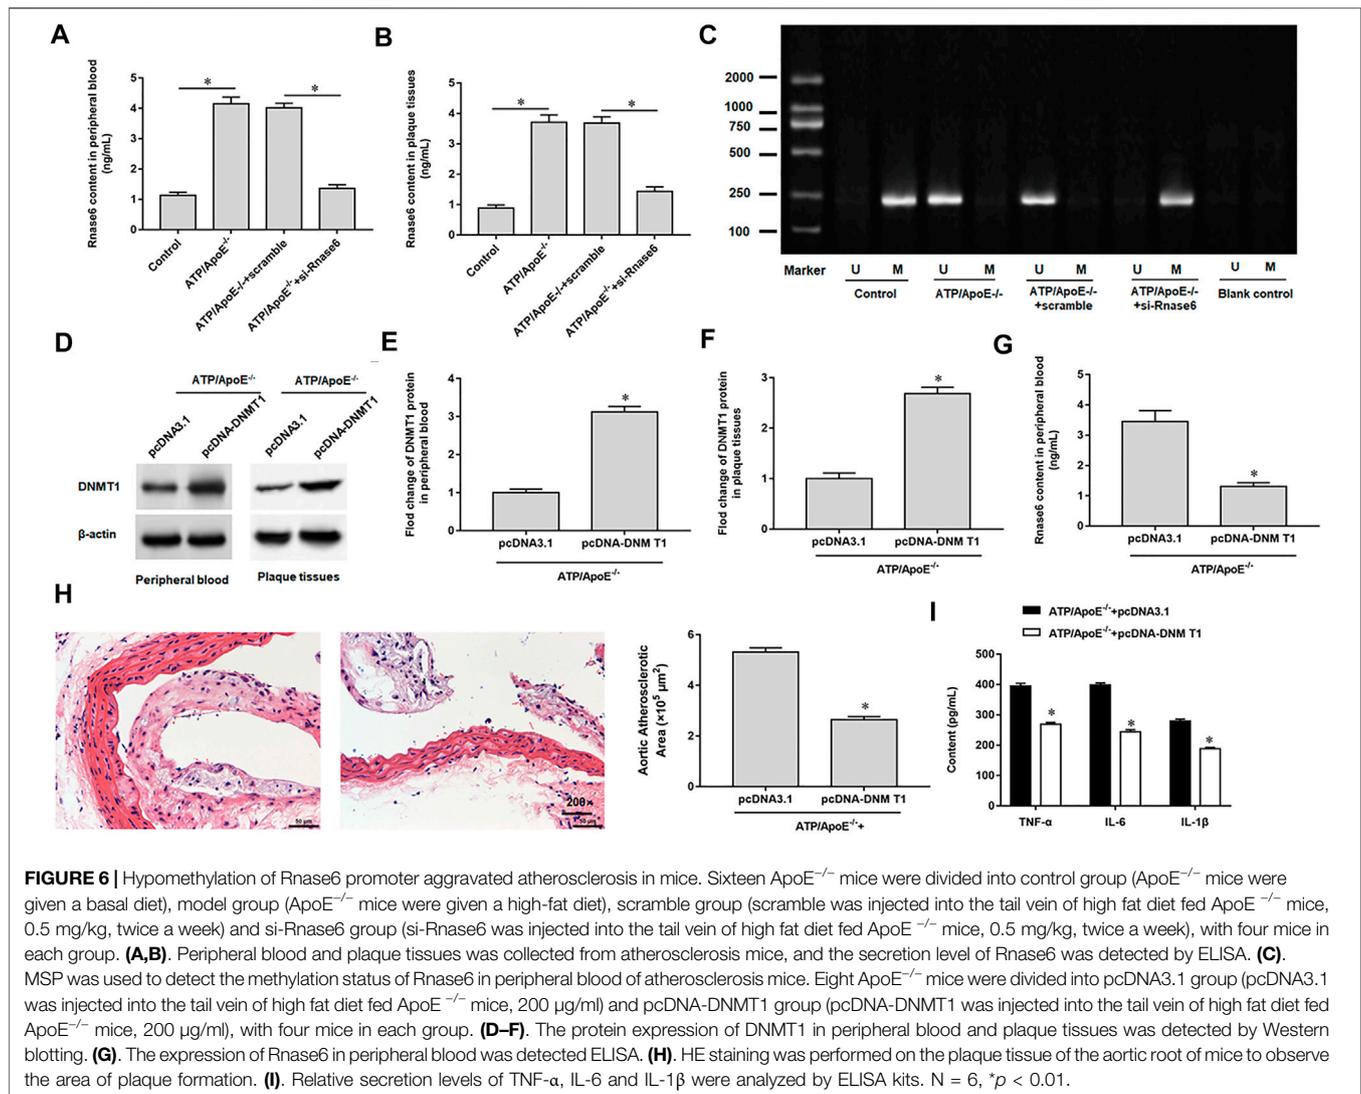

Rnase6, a protein belonging to the superfamily, is considered the only vertebrate specific enzyme known to have a wide range of physiological functions, including digestion, cytotoxicity, angiogenesis, male reproduction, and host defense. In this study, we found that the expression of Rnase6 was up-regulated in the peripheral blood and plaque tissues of atherosclerotic patients, but its promoter methylation was weakened, suggesting that abnormal Rnase6 promoter methylation is involved in the occurrence and development of atherosclerosis. Therefore, we promoted Rnase6 promoter methylation in OX-LDL-induced MOVAS cells, and the results suggested that enhancing Rnase6 promoter methylation inhibited the expression of Rnase6, attenuated the proliferation and migration ability of MOVAS cells, and reduced the secretion of

proinflammatory factors and ROS content. Similarly, interfering with Rnase6 expression in ApoE knockout mice fed a high-fat diet, we found that Rnase6 gene methylation was enhanced in peripheral blood. In addition, promoting Rnase6 promoter methylation significantly inhibited the formation of plaque tissue and alleviated atherosclerosis in mice.

The phosphoinositide 3 kinase (PI3K) protein family is a dimer consisting of the regulatory subunit p85 and the catalytic subunit p110. When it binds to the growth factor

receptor, it can change the protein structure of Akt and activate it, and activate or inhibit the activity of a series of downstream substrates by phosphorylation, thereby regulating the phenotypes of cell proliferation, differentiation, apoptosis and migration. Studies have reported that downregulation of Lnc00113 expression significantly inhibits the proliferation, survival and migration of vascular smooth muscle cells and endothelial cells, and the expression of phosphorylated proteins of PI3K,

Akt and mTOR in cells is also inhibited (Yao, et al., 2018). Liu et al. demonstrated through *in vitro* and *in vivo* studies that quercetin can attenuate high fructose feeding-induced atherosclerosis in mice by inhibiting inflammation and cell apoptosis through ROS-regulated PI3K/AKT signaling pathway (Lu, et al., 2017). A study showed that the expression of miR-126 was decreased in OX-LDL-treated HUVECs, and overexpression of miR-126 reversed OX-LDL-induced HUVECs injury and impaired autophagic flux by blocking the PI3K/Akt/mTOR signaling pathway, thereby reducing the damage of atherosclerotic endothelial cells (Tang and yang, 2018).

In conclusion, our study confirmed that Rnase6 promoter hypomethylation accelerated the proliferation, migration and inflammatory infiltration of injured vascular smooth muscle cells and aggravated atherosclerosis in mice by activating the PI3K/AKT/mTOR signaling pathway, which provided more ideas for finding potential therapeutic targets for atherosclerosis.
