Hepatocellular carcinoma (HCC) is one of the most commonly diagnosed and malignant cancers worldwide. Conventional therapy strategies may not completely eradicate the tumor and may cause side effects during treatment. Nano-catalytic therapy, as a novel strategy, has attracted a great deal of attention. This study aimed to synthesize a multifunctional magneto-gold nanozyme AuNC@Fe₃O₄ and evaluate its anti-cancer potential in HepG2 cells *in vitro*. The characteristics of AuNC@Fe₃O₄ were assessed using a transmission electron microscope, dynamic light scattering, and energy-dispersive X-ray. The photothermal performance and peroxidase (POD)-like activity of AuNC@Fe₃O₄ were detected, using thermal camera and ultraviolet-visible spectrophotometer, respectively. The anti-cancer potential of AuNC@Fe₃O₄ was examined using cell counting kit-8, live/dead cell staining, and apoptosis analysis. Further research on HepG2 cells included the detection of intracellular reactive oxygen species (ROS) and lysosomal impairment. We observed that the AuNC@Fe₃O₄ had a small size, good photothermal conversion efficiency and high POD-like activity, and also inhibited cell proliferation and enhanced cell apoptotic ability in HepG2 cells. Furthermore, the AuNC@Fe₃O₄ enhanced ROS production and lysosomal impairment *via* the synergistic effect of photothermal and nano-catalytic therapies, which induced cell death or apoptosis. Thus, the magneto-gold nanozyme AuNC@Fe₃O₄ may offer a potential anti-cancer strategy for HCC.

1 Introduction

Data from Global Cancer Incidence, Mortality and Prevalence 2020 revealed that liver cancer was the sixth commonly diagnosed and the third lethal cancer worldwide (Sung et al., 2021). China accounted for 23.7% and 30% of the global morbidity and mortality from liver cancer, respectively (Ferlay et al., 2021). It was predicted that between 2020 and 2040, there would be a 55% increase in the number of new cases of liver cancer per year, and the percentage of people who would die from the disease in 2040 would be more than 56.4% of those in 2020 (Rumgay et al., 2022). Primary liver cancer can be classified into three types: cholangiocarcinoma, hepatocellular carcinoma (HCC), and a combination of the two, with HCC accounting for approximately 90% of all cases (Llovet et al., 2016). HCC progression is

influenced by several risk factors, such as alcohol abuse, smoking, toxic chemicals, and hepatitis virus (especially for HBV) infections (Yang et al., 2019). Owing to the absolute number of HBV-infected populations (Liu et al., 2016), the mortality rate of HBV-related liver cancer was consistently higher than the global level (Liu et al., 2019), which increased the burden of HCC in China.

In most cases, conventional treatments, such as surgery, radiation, and chemotherapy, do not completely eradicate the tumor and may cause side effects during treatment, such as cancer palindromia and drug resistance (Zhu et al., 2016; Xu et al., 2019; Raoul and Edeline, 2020; Liu and Song, 2021). For example, the surgery was initially considered to be used for patients with early-stage HCC; However, over 50% of patients experienced a recurrence within a year following surgery (Gil et al., 2015; Weber et al., 2015). Sorafenib was an option for patients with advanced-stage cancer, however, it was only effective in less than a third of them and caused drug tolerance or cytotoxicity (Llovet et al., 2008; Cheng et al., 2009; Bruix et al., 2012; Anwanwan et al., 2020). Besides surgery and chemotherapy, radiation therapy is a non-invasive and local ablative treatment approach to kill cancer cells. However, the efficiency of radiation therapy is easily limited by radioresistance, due to the DNA damage response and cell cycle checkpoints activation (Yoon and Seong, 2014; Wahl et al., 2016; Sun et al., 2020). Although the traditional strategies of HCC control the growth of HCC and prolong the survival time of patients, it still cannot satisfy their needs. Thus, it is necessary to discover a more efficient treatment approach to improve the quality of life for patients.

In recent years, nano-catalytic therapy, as a new tumor treatment strategy, has attracted the attention of an increasing number of researchers. Nanozymes are nanomaterials that catalyze chemical reactions of substrates under physiological states, obeying the patterns of enzyme kinetics (Wei et al., 2021). In 2007, Yan's team was the first to report that magnetic nanoparticles Fe_3O_4 possessed peroxidase (POD)-like activity, and proposed the concept of nano-catalysis (Gao et al., 2007). Furthermore, Shi *et al.* innovatively paved the way for further applications of nanoparticles in tumor nano-catalytic therapy, by disrupting the Fenton reaction that induced H_2O_2 disproportionation for •OH generation (Zhang et al., 2016). Currently, nano-catalytic therapy and photothermal therapy (PTT) are frequently employed in the treatment of tumors. The integration of PTT and nano-catalytic therapy has contributed to improving their cancer therapy efficiency. For instance, hyperthermia promoted the enzymatic activity of Fe_3O_4 nanozyme to generate more •OH, and simultaneously, •OH heightened the therapeutic impact of PTT (Wu et al., 2019; Zuo et al., 2022). It has also been reported that the Fe_3O_4@ZIF-8/GOx@MnO_2 hybrid nanozyme can enhance the efficiency of nanoparticles in anti-tumor therapy by combining multiple therapeutics (Zhang et al., 2021b).

Fe_3O_4 and Au nanoparticles, as is well known, demonstrated the unique characteristics of a high photothermal effect and POD-like activity (Zeng et al., 2013; Vallabani et al., 2017; Ghosh et al., 2022; Huang et al., 2022). Encouraged by the aforementioned description, we wonder if AuNC@Fe_3O_4 which has been employed as magnetic resonance imaging/com-puterized tomography multimodal imaging contrast agents of cancer owing to their high relaxivity value and excellent contrast enhancement (Wang et al., 2016b), also

retains the photothermal and catalytic ability, or is beneficial to cancer therapy.

In this study, we synthesized multifunctional magneto-gold nanozyme AuNC@Fe_3O_4 and evaluated their anti-cancer ability in HCC cells *in vitro*. The AuNC@Fe_3O_4 exhibited high photothermal effect and POD-like activity. The results also reflected the influence of AuNC@Fe_3O_4 on engendering cell death and apoptosis. Furthermore, the synergistic effect of PTT and nano-catalytic therapy on reactive oxygen species (ROS) and lysosomal impairment in HepG2 cells were also studied.

2 Materials and methods

2.1 Materials and reagents

Ferric slat, gold (III) chloride (HAuCl4), other reagents related to AuNC@Fe_3O_4 synthesis and 3,3′,5,5′-Tetramethylbenzidine (TMB) were purchased from Sigma, Inc. (St. Louis, United States). H_2O_2 solution and different pH buffer solutions (pH = 2, 3, 4, 5, 6, 7, 8, and 9) were bought from Aladdin (Shanghai, China). Human umbilical vein endothelial cells (HUVEC), human HCC cell lines (HepG2 cells) and the specific culture mediums for the two cell lines were purchased from Procell (Wuhan, China). Cell Counting Kit-8 (CCK-8) was obtained from Sangon Biotech (Shanghai, China). 2′,7′-Dichlorodihydrofluorescein diacetate (DCFH-DA) was obtained from MedChemExpress (New Jersey, United States). Calcein-AM/propidium iodide (PI) kit, Annexin V-FITC apoptosis detection kit, Lyso-Tracker Red kit and Hoechst 33342 staining solution were purchased from Beyotime. Inc. (Shanghai, China).

2.2 AuNC@Fe_3O_4 synthesis

The AuNC@Fe_3O_4 was synthesized according to previous methods (Wang et al., 2016b). AuNC was initially synthesized and coated with poly (vinyl pyrrolidone) (PVP). Subsequently, PVP was replaced with 2-aminoethanethiol, and AuNC was transformed into AuNC-NH2 for interacting with carboxyl group functionalized Fe_3O_4 nanoparticles. The ultra-small Fe_3O_4 particles were prepared. To produce Fe_3O_4-COOH, ferric slats were vigorously stirred in pre-prepared polymer poly (acrylic acid) (PAA) solution. N-(3-Dimethylaminopropyl)-N-ethylcarbodiimide and N-hydroxysuccinimide activated the Fe_3O_4-COOH, which then reacted with AuNC-NH$_2$ to generate AuNC@Fe_3O_4. The AuNC@Fe_3O_4 was centrifuged, washed with ethanol and water, and then dispersed in ddH$_2$O with different concentrations for further experiments.

2.3 AuNC@Fe_3O_4 characterization

The size of AuNC or AuNC@Fe_3O_4 nanoparticles was analyzed using a transmission electron microscope (TEM). Dynamic light scattering (DLS) was applied to detect hydrodynamic particle diameter and intensity of AuNC@Fe_3O_4 nanoparticles on a Malvern Zetasizer NANO ZS. Energy-dispersive X-ray (EDX)

was utilized to analysis the element of AuNC@Fe$_3$O$_4$ nanoparticles on a FEI TECNAI G20 high-resolution TEM.

2.4 AuNC@Fe$_3$O$_4$ photothermal performance *in vitro*

To investigate the photothermal effect of the magneto-gold nanoparticles, First, 200 µl of AuNC@Fe$_3$O$_4$ solution with distinct concentrations (0, 50, 100, 200, 300, 400, and 500 µg/ml) was exposed to 808 nm laser at 1.0 W for 720 s; Second, 200 µl of AuNC@Fe$_3$O$_4$ solution with concentration of 50 µg/ml was exposed to 808 nm laser at different powers (1.0, 1.2, and 1.4 W) for 720 s. The thermal image and temperature change were recorded at different times by an infrared (IR) thermal camera (Fotric 220). As a control, ddH$_2$O was irradiated under the same conditions.

To investigate the photothermal stability of the magneto-gold nanoparticles, AuNC@Fe$_3$O$_4$ aqueous solution (500 µg/ml) was irradiated under 808 nm laser at 1.0 W for 420 s, then the irradiation was turned off. After that, the temperature was further measured for another 360 s. The experiment was then repeated four more times. The thermal image and temperature change were recorded at different times by the IR thermal camera (Fotric 220). As a control, ddH$_2$O was irradiated under the same operation.

To evaluate the photothermal conversion efficiency of AuNC@Fe$_3$O$_4$, the data from the cooling periods were calculated, according to previous report (Ren et al., 2015). Briefly, when the system reached energy balance, the equation was:

$$\sum_i m_i C_{p,i} \frac{dT}{dt} = Q_{AuNC@Fe_3O_4} + Q_s - Q_{loss} \tag{1}$$

where Cp and m were the heat capacity and mass of AuNC@Fe$_3$O$_4$ solution, respectively. T was the temperature of the AuNC@Fe$_3$O$_4$ solution. $Q_{AuNC@Fe_3O_4}$ represented energy absorbed by AuNC@Fe$_3$O$_4$ nanoparticles. Q_s represented the energy absorbed by ddH$_2$O. Q_{loss} was the heat lost to the surroundings.

The equation for $Q_{AuNC@Fe_3O_4}$ was:

$$Q_{AuNC@Fe_3O_4} = I\left(1 - 10^{-A_\lambda}\right)\eta \tag{2}$$

where I represented the laser power density, A_λ denoted the absorbance of AuNC@Fe$_3$O$_4$ solution under 808 nm in a 96-well plate, and η represented its photothermal conversion efficiency.

The equation for Q_{loss} was

$$Q_{loss} = hA\Delta T \tag{3}$$

where A was the surface area of the container, h denoted the heat transfer coefficient; ΔT represented the temperature changes, expressed as T-T$_{surr}$ (where T and T$_{surr}$ represent the solution and surrounding air temperature, respectively).

When heating ddH$_2$O, the heat input and output reached energy balance at the maximum steady-state temperature, therefore the equation for Q_s was:

$$Q_s = Q_{loss} = hA\Delta T_{max,H_2O} \tag{4}$$

where $\Delta T_{max,H_2O}$ was the temperature changes of ddH$_2$O.

When the system reached its maximum balanced temperature, the energy input (the heat absorbed by AuNC@Fe$_3$O$_4$ and ddH$_2$O) was equal to the heat lost into the surrounding, and the equation could be:

$$Q_{AuNC@Fe_3O_4} + Q_s = Q_{loss} = hA\Delta T_{max,mix} \tag{5}$$

where $\Delta T_{max,mix}$ was the changed temperature of the AuNC@Fe$_3$O$_4$ solution.

According to Eqs 2, 4, 5, η was:

$$\eta = \frac{hA\Delta T_{max,mix} - hA\Delta T_{max,H_2O}}{I\left(1 - 10^{-A_\lambda}\right)} = \frac{hA\left(\Delta T_{max,mix} - \Delta T_{max,H_2O}\right)}{I\left(1 - 10^{-A_\lambda}\right)} \tag{6}$$

To calculate the unknown hA, θ was introduced, and could be expressed as following:

$$\theta = \frac{\Delta T}{\Delta T_{max}} \tag{7}$$

Adding Eq. 7 into Eq. 1, the new equation could be:

$$\frac{d\theta}{dt} = \frac{hA}{\sum_i m_i C_{p,i}} \left(\frac{Q_{AuNC@Fe_3O_4} + Q_s}{hA\Delta T_{max}} - \theta \right) \tag{8}$$

During the cooling period, the $Q_{AuNC@Fe_3O_4} + Q_s = 0$ in Eq. 8 was:

$$dt = -\frac{\sum_i m_i C_{p,i}}{hA} \frac{d\theta}{\theta} \tag{9}$$

which could be changed as following:

$$t = -\frac{\sum_i m_i C_{p,i}}{hA} \ln\theta \tag{10}$$

where $\frac{\sum_i m_i C_{p,i}}{hA}$ was calculated by time versus -ln(θ) plot. Since the mass of AuNC@Fe$_3$O$_4$ (1×10^{-7} kg) was relatively small when compared to that of ddH$_2$O (m = 2×10^{-4} kg), its m and Cp were neglected. The value of hA was then calculated using m_{H_2O} of 2×10^{-3} kg; C_{p,H_2O} of 4.2×10^3 J/(Kg.°C). Furthermore, the η of AuNC@Fe$_3$O$_4$ was determined by substituting the value of hA and other parameters into Eq. 6. The values of other parameters were as follows: I = 2.3 W/cm^2, A_λ = 0.105, $\Delta T_{max,mix}$ = 25.3, and $\Delta T_{max,H_2O}$ = 0.1.

2.5 POD-like activity assay

To evaluate the catalytic properties of AuNC@Fe$_3$O$_4$, AuNC@Fe$_3$O$_4$ (final concentration: 0, 5, 10, 20, 50, and 100 µg/ml), TMB (final concentration: 0.4 mM), and H$_2$O$_2$ (final concentration: 50 µM) was added into a final volume of 500 µl of phosphate-buffered saline (PBS) solution. The absorbance of the buffer was measured using an ultraviolet-visible (UV-vis) spectrophotometer at 500–800 nm. The POD-like activity assay of AuNC@Fe$_3$O$_4$ at varying pH levels (pH = 2, 3, 4, 5, 6, 7, 8, and 9) was performed in the presence of H$_2$O$_2$ and TMB in PBS solution, and the absorbance at 652 nm was detected by a microplate reader.

2.6 POD-like catalytic kinetic determination

When TMB was used as a substrate, the AuNC@Fe$_3$O$_4$ (final concentration: 50 µg/mL), TMB (final concentration: 0.0, 0.2, 0.4, 0.6, and 0.8 mM), and H$_2$O$_2$ (final concentration: 50 µM) was added into a final volume of 100 µl of PBS solution. The absorbance at 652 nm was detected by a microplate reader.

When H_2O_2 was used as a substrate, the AuNC@Fe$_3$O$_4$ (final concentration: 50 μg/ml), H_2O_2 (final concentration: 0, 10, 20, 30, 40, 50, 60, 70, and 80 μM) and TMB (final concentration: 0.4 mM) was added into a final volume of 100 μl of PBS solution. The absorbance at 652 nm was detected by a microplate reader.

Based on Michaelis-Menten Eq. 11 and saturation curve, the V_{max} and Michaelis-Menten constant could be calculated,

$$\frac{1}{V} = \frac{K_m}{V_{max}} \frac{1}{[s]} + \frac{1}{V_{max}} \quad (11)$$

and the V was calculated using Eq. 12:

$$V = \frac{A}{(b \times \mathcal{E}_{652\,nm} \times t)} \quad (12)$$

where A was the absorbance of the reaction system at 652 nm. t = 600 s, which was the reaction time. b = 0.3125 cm, which was the light path in the reaction solution, and $\mathcal{E}_{652\,nm}$ = 39,000 M^{-1} cm^{-1} (Dashtestani et al., 2019).

2.7 Cell viability assay

The HepG2 and the HUVEC cells were cultured to assess the cytotoxicity of AuNC@Fe$_3$O$_4$ through CCK-8 assay. 4000 of cells were cultured at 96-well plate well overnight at 37°C in a humidified incubator with 5% CO_2. Subsequently, 100 μl of fresh medium with distinct concentrations of AuNC@Fe$_3$O$_4$ (0, 10, 20, 30, 40, and 50 μg/ml) was changed and cultured for 24 h. The CCK-8 solution (final volume: 10 μl) was added into 100 μl of medium, and incubated for 2 h. Then, the absorbance of medium was detected at 450 nm.

2.8 Live/dead cell staining assay

HepG2 cells were cultured overnight in a 12-well plate with 500 μl of culture medium. The cells were then treated with PBS or AuNC@Fe$_3$O$_4$ (50 μg/ml) for 12 h. Then, the cells were cultured for an additional 12 h after either being irradiated by an 808 nm laser for 5 min at 1.4 W or not. The culture medium was then removed, and cells were washed once with PBS and incubated with 500 μl stain solution for 15 min. Finally, the cells were washed thrice with PBS and photographed by an inverted fluorescence microscope.

2.9 Apoptosis analysis

To investigate the ability of AuNC@Fe$_3$O$_4$ for inducing cell apoptosis, HepG2 cells were quantitatively detected by a flow cytometer. The cells were initially seeded into a 6-well plate and treated under different conditions for 24 h. They were collected with 0.25% trypsin and washed thrice with ice-cold PBS. Subsequently, these cells were resuspended in 195 μl of binding buffer. Ten microliters of PI and 5 μl of Annexin V-FITC were added, and the mixture was incubated for 20 min at room temperature, and cells were detected by flow cytometer.

2.10 Intracellular ROS detection

The intracellular POD-like catalytic ability of AuNC@Fe$_3$O$_4$ was detected using DCFH-DA. Except for an additional 4 h of culture, the method used for the laser-irradiated groups was similar to the treatment described above. Furthermore, 1 ml of PBS with DCFH-DA (5 μM) was added, and the mixture was incubated for another 30 min at 37°C in a humidified incubator with 5% CO_2. The wells were then washed thrice with PBS to remove the excess dye and photographed by an inverted fluorescence microscope.

2.11 Lysosomal impairment assay

After treatment, lysosomes and cell nuclei were stained with Lyso-Tracker Red and Hoechst 33342, respectively, according to the manufacturer's instructions. Subsequently, an inverted fluorescence microscope was used to capture images of cells.

2.12 Statistical analysis

Statistical analysis was achieved by GraphPad Prism version 8 (GraphPad Software, United States). Results were represented as mean ± standard deviation. The student t-test was used to compare the means of multiple groups. The statistical significances were as follows: * $0.01 < p < 0.05$, ** $0.001 < p < 0.01$, and *** $p < 0.001$.

3 Results and discussion

3.1 Synthesis and characterization of AuNC@Fe$_3$O$_4$

The structure and characteristics of AuNC and AuNC@Fe$_3$O$_4$ were determined by TEM. The results demonstrated that the diameter of AuNC and AuNC@Fe$_3$O$_4$ were 25–40 and 50–100 nm, respectively, with high uniformity and no agglomeration (Figures 1A, B). DLS was used to confirm the size of AuNC@Fe$_3$O$_4$, and the average hydrodynamic size distribution of these nanoparticles was approximately 55 nm (Figure 1C). The increase in the hydrodynamic size might be owing to the attachment of Fe$_3$O$_4$ to the surface of the AuNC. Elemental mapping analysis revealed the presence of the atoms Au, Fe and O, proving that AuNC@Fe$_3$O$_4$ was successfully formed (Figure 1D; Table 1). The "-CO-NH-", that came from the reaction of Fe$_3$O$_4$-COOH and AuNC-NH$_2$ and the carbon-coated brace used during sample preparation or analysis might have contributed to the existence of C element that was also present (Phongtongpasuk et al., 2016).

3.2 Photothermal performance of AuNC@Fe$_3$O$_4$

The thermal camera was used to investigate the photothermal conversion capabilities of AuNC@Fe$_3$O$_4$. The temperature changes of AuNC@Fe$_3$O$_4$ solution with different concentrations under

TABLE 1 The statistics of elements analysis for AuNC@Fe$_3$O$_4$ by energy-dispersive X-ray (EDX).

Compound	Element	Weight (%)
AuNC@Fe$_3$O$_4$	Au	23.1
	Fe	29.4
	O	42.4
	C	5.1

808 nm laser irradiation at 1.0 W for 360 s were recorded. As depicted in Figure 2A, the temperature of the solution increased in a concentration- and time-dependent pattern. For example, the temperature of different concentrations of AuNC@Fe$_3$O$_4$ solution reached steady statue at 8 min. The temperature of AuNC@Fe$_3$O$_4$ solution (500 μg/ml) was changed significantly from 25.9°C to 52.3°C compared with the neglected increase in that of ddH$_2$O (from 26.0°C to 26.5°C), indicating the good photothermal response of AuNC@Fe$_3$O$_4$. For further investigation, the AuNC@Fe$_3$O$_4$ solution (50 μg/ml) was irradiation at different powers (1.0, 1.2, and 1.4 W). The laser power was increased from 1.0 to 1.4 W, which resulted in a significant increase in the temperature of the AuNC@Fe$_3$O$_4$ solution. A temperature of 45.3°C was achieved after 10 min of 808 nm laser irradiation at 1.4 W (Figure 2B). PTT, a promising cancer treatment strategy, converts light energy into heat to generate an area of hyperthermia, where tissues can be exposed to high temperatures (from 42°C to 45°C), which can damage or kill tumor cells (Tchouagué et al., 2019; Qu et al., 2022). The results of Figures 2A, B suggested a potential application of AuNC@Fe$_3$O$_4$ in anti-tumor.

Additionally, five cycles of the "On and Off" model were used to measure the temperature curve of the AuNC@Fe$_3$O$_4$ solution to assess its photothermal stability. The AuNC@Fe$_3$O$_4$ showed excellent photothermal stability since the temperature was raised to 52.9 °C and there was no reduction in the temperature rise following laser irradiation during the five cycles (Figure 2D).

Moreover, the average of the data from the five cooling periods was used to get the photothermal conversion efficiency (η) of AuNC@Fe$_3$O$_4$. The plot of the time value and −ln (θ) was displayed in Figure 2E, and its slope was 99.526. Using Eqs 6, 10, the η of AuNC@Fe$_3$O$_4$ was calculated to be 39.58%, which was similar with or higher than the PPT reagents previously reported, such as, EA-Fe@BSA NPs (31.2%) (Tian et al., 2020), Fe$_3$O$_4$@Carbon@Platinum-Chlorin e6 (28.28%) (Xu et al., 2022b), Au nanorods (22%) (Zeng et al., 2013), Au nanoshells (13%) (Hessel et al., 2011), PANi@Au (40.4%) and Au nanoparticles (21.7%) (Zhang et al., 2021a).

Collectively, these findings suggested that AuNC@Fe$_3$O$_4$ exhibited good photothermal conversion and photothermal stability, which implied a promising application in PTT for tumors.

3.3 POD-like activity of AuNC@Fe$_3$O$_4$

It was reported that Au and Fe$_3$O$_4$ nanoparticles demonstrated POD-like enzyme activity (Zandieh and Liu, 2021), therefore it was necessary to investigate whether the AuNC@Fe$_3$O$_4$ possessed similar characteristics. The peroxidase mimicking activity of AuNC@Fe$_3$O$_4$ was validated by TMB. TMB could be oxidized to blue oxTMB by •OH and detected at 652 nm, using UV-vis spectrophotometer (Zhu et al., 2022). As presented in Figure 3A,
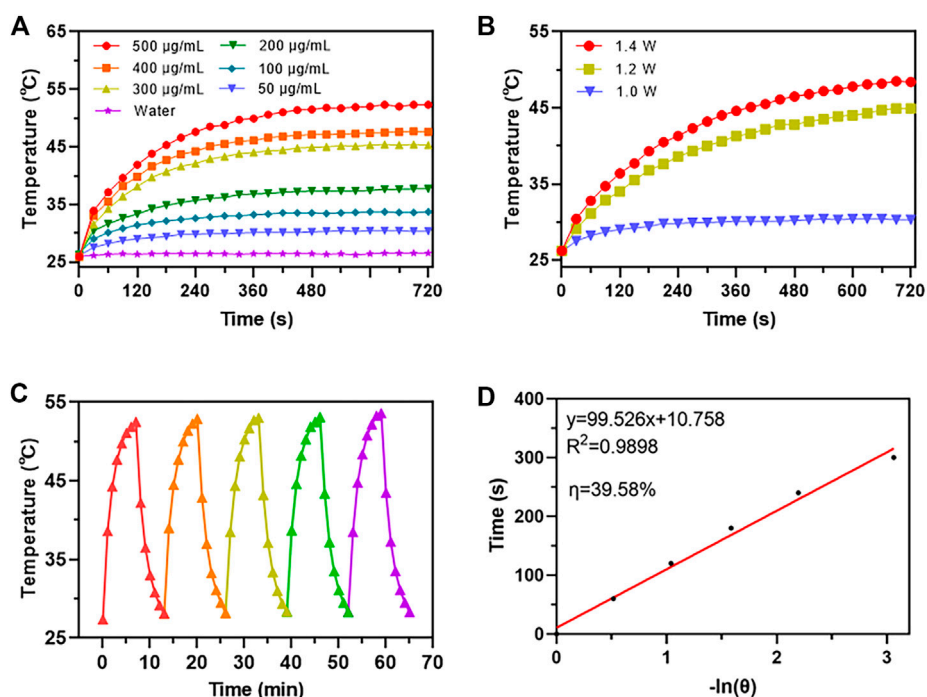

FIGURE 2
Photothermal performance analysis of AuNC@Fe$_3$O$_4$. **(A)** Temperature change curves of water and AuNC@Fe$_3$O$_4$ aqueous solution after different treatments **(B)** Temperature change curves of AuNC@Fe$_3$O$_4$ after different treatments **(C)** Photostability of AuNC@Fe$_3$O$_4$ solution under irradiation for five cycles. **(D)** Time versus -ln(θ) plot of the AuNC@Fe$_3$O$_4$ solution.

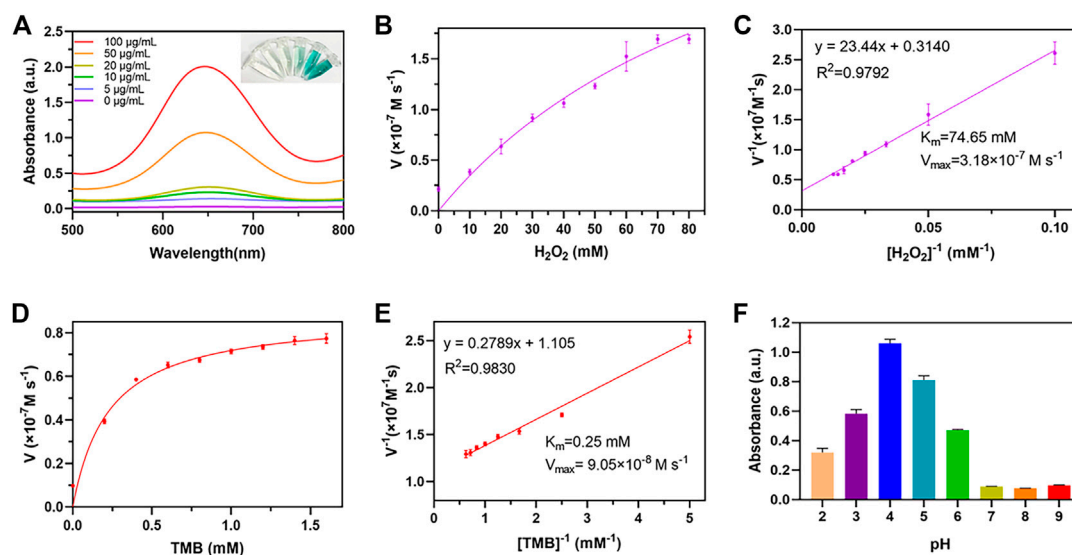

FIGURE 3
POD-like activity assay of AuNC@Fe$_3$O$_4$. **(A)** Ultraviolet-visible (UV-vis) absorption spectra of the reaction system with different concentrations. **(B)** Michaelis-Menten curve of AuNC@Fe$_3$O$_4$ for H$_2$O$_2$. **(C)** Lineweaver-Burk plotting of AuNC@Fe$_3$O$_4$ for H$_2$O$_2$. **(D)** Michaelis-Menten curve of AuNC@Fe$_3$O$_4$ for TMB. **(E)** Lineweaver-Burk plotting of AuNC@Fe$_3$O$_4$ for TMB. **(F)** The absorbance of the reaction system at 652 nm under different pH values.

the groups with different concentrations of AuNC@Fe$_3$O$_4$ had varying absorbance intensities at 652 nm. The group of AuNC@Fe$_3$O$_4$ with 100 µg/ml showed the strongest signal at 652 nm,

followed by the group with 50 µg/ml. The intensity of absorbance tested with H$_2$O displayed no peak at 652 nm. These findings, which indicated that the AuNC@Fe$_3$O$_4$ possessed POD-like enzyme

activity, were further verified by the inset digital photos (Figure 3A). To further confirm the POD-like enzyme specificity of AuNC@ Fe$_3$O$_4$, the UV-vis absorption spectra of the reaction system with varying conditions was collected. It was observed from Supplementary Figure S1 that absorbance peak of the AuNC@ Fe$_3$O$_4$+TMB or AuNC@Fe$_3$O$_4$+H$_2$O$_2$ group was negligible. In the absence of AuNC@Fe$_3$O$_4$, the TMB + H$_2$O$_2$, TMB or H$_2$O$_2$ group showed no significant absorbance peak at 652 nm, which was consistent with the AuNC@Fe$_3$O$_4$ only group. The results suggested that, except AuNC@Fe$_3$O$_4$, other components in the reaction system could hardly catalyzed the conversion of H$_2$O$_2$ to •OH and oxidized TMB, which indicated AuNC@Fe$_3$O$_4$ exhibited a specific activity of POD-like enzyme.

Kinetic parameters were analyzed to quantitate the POD-like activity of AuNC@Fe$_3$O$_4$ using the initial rate method (Gao et al., 2017). First, the absorbance of the system was measured, while varying the concentrations of H$_2$O$_2$ concentrations from 0 to 80 mM and maintaining a TMB concentration of 0.4 mM (Supplementary Figure S2). Second, the velocity of reaction was calculated according to Eq. 12 and the plot was consistent with traditional Michaelis-Menten curve (Figure 3B), which demonstrates that the catalytic reaction rate increased with the growth of substrate concentration and achieved steady state at high concentrations (Huang et al., 2022). Third, after Lineweaver-Burk fitting, the enzyme kinetic parameters, such as Michaelis-Menten constants (K$_m$) was calculated to be 47.65 mM and the maximum reaction velocity (V$_{max}$) was 3.18×10^{-7} M s^{-1} (Figure 3C). Forth, the absorbance of the solution was measured at 652 nm while varying TMB concentrations and maintaining H$_2$O$_2$ concentration as a constant (Supplementary Figure S3). Last, the K$_m$ and V$_{max}$ were 0.25 mM and 9.03×10^{-8} M s^{-1} respectively, and the results were presented in Figures 3D, E.

When the H$_2$O$_2$ was used as substrate, the velocity of AuNC@ Fe$_3$O$_4$ was faster than that of Fe$_3$O$_4$ (Vallabani et al., 2017), and K$_m$ value that was lower than that of Fe$_3$O$_4$ (Vallabani et al., 2017). Similarly, when the TMB was used as substrate, AuNC@Fe$_3$O$_4$ had a velocity that was faster than that of Au NRT, Au NC, Au NS, and horseradish peroxidase (Ghosh et al., 2022), and its value of K$_m$ was also lower than those of them. In the catalytic reaction system, the K$_m$ represents the affinity between the enzyme and substrates, and the lower the K$_m$, the higher enzyme affinity (Jiang et al., 2018). Therefore, the results suggested that the catalytic ability and the affinity between AuNC@Fe$_3$O$_4$ nanozyme and substrates (such as TMB and H$_2$O$_2$) was stronger than that of Fe$_3$O$_4$ and Au nanoparticles. The following factors may contribute to the significant increase in POD-like activity of AuNC@Fe$_3$O$_4$ nanoparticles: the electronic structure of the interfaces between the Fe$_3$O$_4$ and Au, the synergistic effect, and polarization effects from Au to Fe$_3$O$_4$ (Lee et al., 2010; Sun et al., 2013; Wang et al., 2016a).

Considering the complex tumor microenvironment, such as hypoxia and weak acidity (Li et al., 2020; Zhao et al., 2021), it was unclear whether AuNC@Fe$_3$O$_4$ exhibits POD-like enzyme activity even at low pH. At low pH values ranging from 2 to 6, the AuNC@Fe$_3$O$_4$ exhibited higher POD-like enzyme activity, and the optional pH was 4. When the pH was higher than 7, the POD-like enzyme activity was reduced dramatically (Figure 3F). The results hinted that AuNC@Fe$_3$O$_4$ might have significantly varied POD-like enzyme activity between distinct parts of normal (pH = 7.4) and cancer tissues (pH = 6.5), especially for lysosomes (pH = 4.5–5.5) and endosomes (pH = 5.5–6.8) (Kuppusamy et al., 2002; Wojtkowiak et al., 2011).

Overall, these findings provided evidence for the high POD-like catalytic activity of AuNC@Fe$_3$O$_4$ nanozyme and implied potential catalytic ability in tumor.

3.4 *In vitro* anti-tumor effect of AuNC@ Fe$_3$O$_4$

It is important to examine the biocompatibility of AuNC@Fe$_3$O$_4$ before performing further clinical applications. Therefore, HepG2 and HUVEC cells were incubated with AuNC@Fe$_3$O$_4$ at varying concentrations for 24 h to estimate the cytotoxicity using CCK-8 assay. Low concentrations of AuNC@Fe$_3$O$_4$ did not affect the survival rate of HepG2 cells; however, at 40 and 50 µg/ml, the viability of cells decreased to 77% and 60%, respectively (Figure 4A). In contrast, the viability of HUVEC cells was not drastically affected by AuNC@Fe$_3$O$_4$ after 24 h incubation at the varying treatments (Figure 4B). The findings indicated that AuNC@Fe$_3$O$_4$ was not toxic to normal cells at the concentration ranging from 0 µg/ml to 50 µg/ ml and demonstrated good biocompatibility. The reason why AuNC@Fe$_3$O$_4$ showed more sensitive to HepG2 could be attributed to the fact that the pH of the tumor was lower than that of normal tissues (Kuppusamy et al., 2002; Wojtkowiak et al., 2011) and that the AuNC@Fe$_3$O$_4$ had higher POD-like enzyme activity in a lower pH reaction system, which meant it produced more •OH, which could be lethal to cells (Cui et al., 2018; Malfanti et al., 2022).

To explore the anti-tumor effect of AuNC@Fe$_3$O$_4$, the live/dead cell staining assay was utilized. There were nearly no dead cells in the PBS and PBS + NIR (near-infrared) groups; However, when the cells were treated with AuNC@Fe$_3$O$_4$ or AuNC@Fe$_3$O$_4$+NIR, the number of dead cells increased significantly, with the last group having the most cell death (Figure 4C). To further verify this result, the flow apoptosis assays of HepG2 cells with different conditions was conducted. As depicted in Figures 4D, E; Supplementary Table S1, the results indicated that approximately 51% apoptotic cells (Q2+Q3) were observed in the AuNC@Fe$_3$O$_4$+NIR group, which was greater than other groups.

The results revealed that AuNC@Fe$_3$O$_4$ displayed good biocompatibility, and the laser irradiation augmented the anti-tumor ability of AuNC@Fe$_3$O$_4$.

3.5 ROS and lysosomal impairment induced by AuNC@Fe$_3$O$_4$

To confirm the synergistic effect of PTT and POD-like enzyme catalytic activity of AuNC@Fe$_3$O$_4$, the production of the ROS in HepG2 cells was validated using the DCFH-DA probe. As reported, DCFH-DA crossed the cell membrane and was subsequently oxidized to DCF with green fluorescence (Afri et al., 2004). It was evident from Figure 5A that the HepG2 cells incubated with AuNC@Fe$_3$O$_4$ exhibited a higher green fluorescence signal than PBS and PBS + NIR, indicating the ability of AuNC@Fe$_3$O$_4$ to effectively
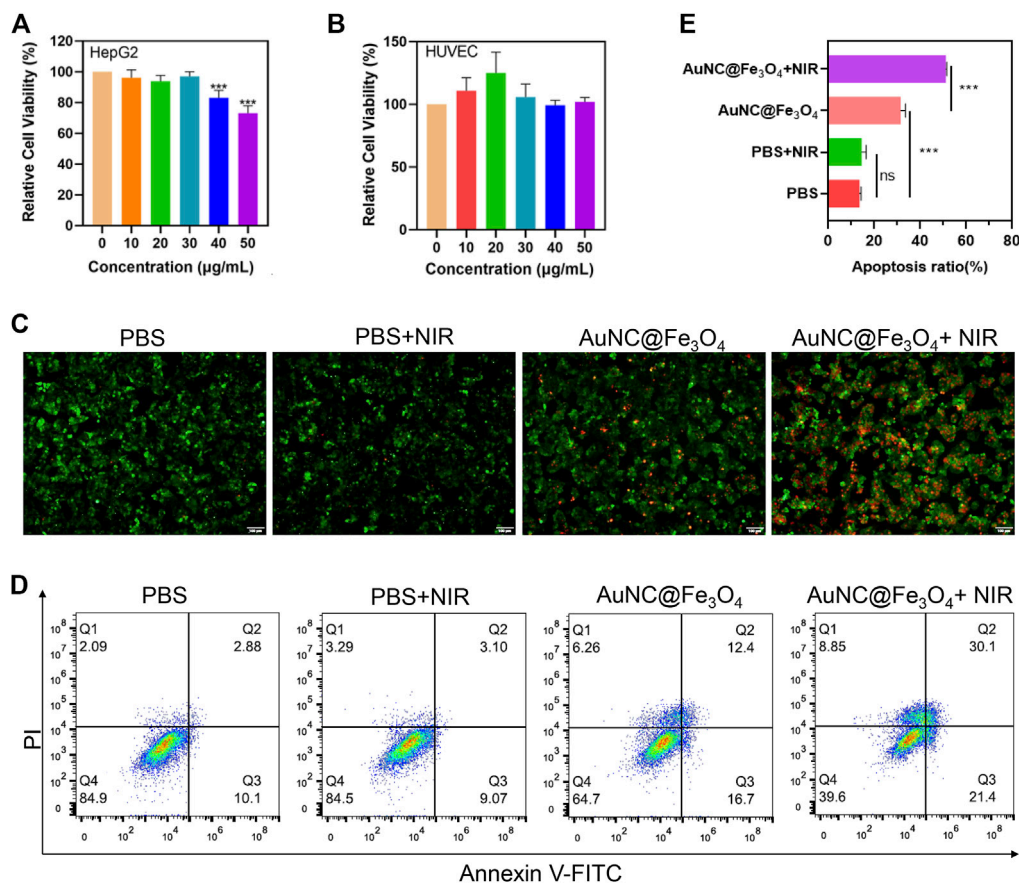

FIGURE 4

Analysis for synergistic effect of photothermal therapy (PTT) and catalytic activity of AuNC@Fe$_3$O$_4$. **(A)** Reactive oxygen species (ROS) detection of HepG2 cells with varying treatments. **(B)** Lysosomal impairment detection of HepG2 cells with varying treatments. Scale bar: 50 μm.

catalyze the conversion of intracellular H_2O_2 into $\bullet OH$ in cancer cells. Compared with the AuNC@Fe$_3$O$_4$ group, the signal of the AuNC@Fe$_3$O$_4$+NIR group was stronger. The similar result was collected by the detection of the absorbance intensities at 652 nm of the reaction system with or without NIR irradiation, using UV-vis spectrophotometer. We found the signal of reaction system with NIR irradiation was higher than that of group without irradiation (Supplementary Figure S4). The results confirmed that photothermal effect enhanced the POD-like enzyme catalytic activity of AuNC@Fe$_3$O$_4$.

The phenomenon could be attributed to the localized surface plasmon resonance (LSPR), which was the collective oscillation of surface free electrons in metal nanoparticles under light irradiation, leading to local heating (also called photothermal effect) and hot carriers (such as hot electrons and hot holes). One hand, energy of hot electrons may transfer to local heating by electron-phonon interactions, causing a rise in temperature (Brongersma et al., 2015). Similar with natural enzymes, the catalytic ability of nanozymes could be enhanced by elevated temperature (Wang et al., 2021; Zhu et al., 2022). Another hand, hot electrons could be transferred from AuNPs to empty orbits of H_2O_2, and activated the H_2O_2 to generate $\bullet OH$ under NIR light irradiation (Wang et al., 2017; Xu et al., 2022a).

It was reported that increased ROS could disrupt normal structure of the lysosomes (Shyam et al., 2021); however, whether the AuNC@Fe$_3$O$_4$ could induce lysosomal impairment remained unknown. The fluorescence images (Figure 5B) demonstrate that the PBS alone and PBS + NIR groups had negligible effects on the lysosomal impairment and that there were more HepG2 cells with lysosomal impairment following incubation with AuNC@Fe$_3$O$_4$. As expected, the lysosomal signal was the weakest in the AuNC@Fe$_3$O$_4$ under laser irradiation group. The results confirmed the synergistic effect of PTT and POD-like enzyme catalytic activity of AuNC@Fe$_3$O$_4$ on lysosomal impairment. Additionally, lysosomal impairment may contribute to an increase in lysosomal membrane permeability, a decrease in lysosomal quantity, a disruption in lysosomal enzyme activities, an increase in ROS levels, and most importantly, the induction of cell apoptosis (Abulikemu et al., 2022).

This at least partly, explained why AuNC@Fe$_3$O$_4$ with or without laser irradiation could cause cell death or apoptosis.

4 Conclusion

In summary, this study aimed to synthesize magneto-gold nanozyme AuNC@Fe$_3$O$_4$ and evaluate its anti-cancer effects for HCC *in vitro*. The AuNC@Fe$_3$O$_4$ showed the typical small size of about 55 nm. Additionally, it demonstrated a high photothermal conversion efficiency and POD-like activity. The CCK-8 results demonstrated that AuNC@Fe$_3$O$_4$ had good biocompatibility and HCC cell-killing ability. Moreover, AuNC@Fe$_3$O$_4$ could synergistically stimulate cell death or apoptosis. Finally, it was observed that magneto-gold nanocomposites could facilitate 808 nm laser irradiation to increase their catalytic ability to produce ROS. This might promote lysosomal impairment, causing cell death or apoptosis. These results suggested that the

AuNC@Fe$_3$O$_4$ may offer a promising anti-cancer strategy for HCC *via* the synergistic effect of PTT and nano-catalytic therapy. Further research is required to investigate the therapeutic efficacy of AuNC@Fe$_3$O$_4$ for HCC *in vivo*.

Data availability statement

The original contributions presented in the study are included in the article/Supplementary Material, further inquiries can be directed to the corresponding author.

Author contributions

XS and GW proposed the conception and design of the study. XS and JL performed the experiments and interpretation of the data. XS and JL drafted the manuscript. GW reviewed and revised the manuscript. All authors read and approve the final manuscript.
