2',5'-oligoadenylate synthase (OAS) is a class of enzymes induced by interferons and mainly encoded by the OAS1, OAS2, and OAS3 genes, which activate the potential RNA enzymes to degrade viral mRNA, inhibit viral protein synthesis and promote apoptosis in virus-infected cells. OAS3 is associated with breast cancer prognosis. However, the expression and prognosis of OAS3 and tumour-infiltrating lymphocytes in pan-cancer remain unknown. In the present study, we have systematically investigated and confirmed the role of OAS3 in tumour immune infiltration, immune escape, tumour progression, response to treatment, and prognosis of different cancer types using various bioinformatics methods. The findings suggest that OAS3 is aberrantly expressed in almost all TCGA cancer types and subtypes and is associated with tumour staging, metastasis, and prognostic deterioration in different tumours. In addition, OAS3 expression is associated with the prognosis and chemotherapeutic outcomes of various cancers. In terms of immune-infiltrating levels, OAS3 expression is positively associated with the infiltration of immunosuppressive cells. These findings suggest that OAS3 is correlated with prognosis and immune-infiltrating levels.

Keywords: OAS3, pancancer analysis, biomarker, tumour microenvironment, prognosis carcinoma

INTRODUCTION

The development and progression of malignancy is a complex process involving several stages (Yang et al., 2019). Malignant tumours are heterogeneous and result from an accumulation of distinct genetic and epigenetic alterations (Lin et al., 2015). Several studies have suggested that genetic and epigenetic alterations can be functionally associated with carcinogenesis (Toyota and Suzuki, 2010; Coppèdè et al., 2014; Grady et al., 2021). The tumor microenvironment (TME) is a complex cellular ecosystem in which tumor, stroma, and immune cells interact dynamically through secreted factors and physical interactions in a dynamic extracellular matrix (Grauel et al., 2020). The complexity of TME results in an interplay of various cellular signalling systems in which tumour cells infiltrate immune cells, making them dysfunctional, and hence unable to initiate any anti-tumour immune

action (Jiang et al., 2015; Thommen and Schumacher, 2018). In addition, the immunosuppressive cellular component of TME may inhibit T-cell responses, antibody production and the induction of cytotoxic T lymphocytes, promoting tumour growth, impairing the immune response, and leading to treatment resistance (Liu and Cao, 2016; Monteran and Erez, 2019). Bioinformatics can accurately capture cell-type-specific profiles and cell–cell interactions at the tissue level, resulting in relevant genomic differences in the diagnosis, staging, prognosis, and therapeutic responses among various tumours.

2'-5'-oligoadenylate synthetase (OAS), an interferon-induced antiviral enzyme, is composed of OAS1, OAS2, OAS3, and OASL. OAS3 plays a critical role in antiviral action and signal transduction, and high OAS3 expression is associated with the poor prognosis of patients with breast cancer (Zhang and Yu, 2020). Owing to the complexity of tumorigenesis, pan-cancer analysis of the expression patterns of target genes and assessment of their correlation with clinical prognosis and potential molecular mechanisms are of great importance. In this study, we performed a pan-cancer analysis to examine the expression profiles of OAS3 in different cancer tissues and identify its underlying molecular mechanisms in the clinical prognosis of tumours.

MATERIALS AND METHODS

Data Collection and Evaluation of OAS3 Expression in Pan-Cancer

RNA sequence data, survival data, and clinicopathologic characteristics of the 33 cancers were obtained from the UCEC online database (<https://xena.ucsc.edu/>), which was obtained from the TCGA database (Tomczak et al., 2015). Using the rma function in the R package, the whole dataset was filtered, and missing and duplicate results were removed and converted to log₂ (TPM + 1). OAS3 sequencing data were

obtained from the GTEx Project and Broad Institute CCLC database to analyse differences between tumours and adjacent normal tissues. In addition, 36 patients with liver hepatocellular carcinoma (LIHC), 30 patients with lung adenocarcinoma (LUAD), and 30 patients with kidney renal papillary cell carcinoma (KIRP) were recruited from the First Affiliated Hospital of Zhengzhou University and Jiading District Central Hospital Shanghai University of Medicine as the validation cohort. The basic clinical characteristics of patients are shown in **Table 1**, **Table 2**, and **Table 3**. All patients provided written informed consent for the data to be included in the study. The study flowchart is presented in **Figure 1**.

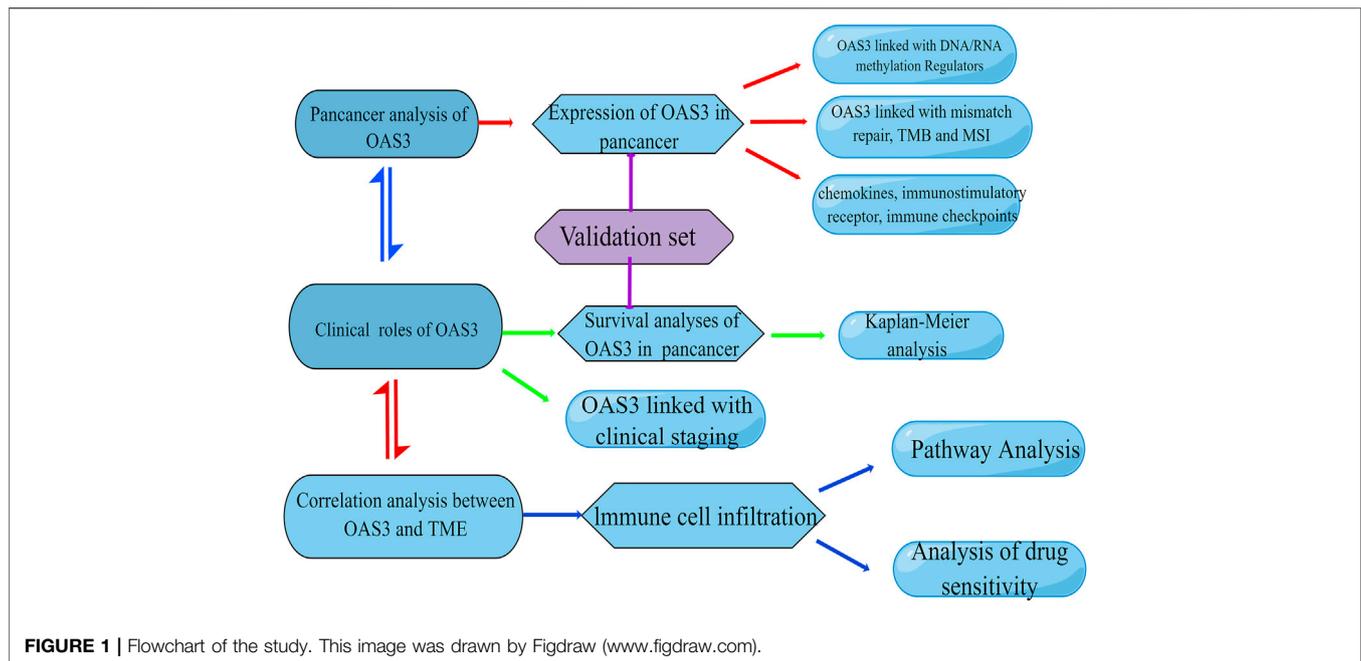

FIGURE 1 | Flowchart of the study. This image was drawn by Figdraw (www.figdraw.com).

Prognostic Significance of OAS3

We used four prognostic indicators (including overall survival [OS], disease-specific survival [DSS], disease-free survival [DFS], and disease progression-free survival [PFS]) and investigated the relationship between OAS3 expression and the prognosis of patients with 33 cancers using forest plots. Survival results were summarised using “forestplot” (R package). Patients were divided into high and low OAS3 expression groups based on the median OAS3 expression. Kaplan–Meier survival analysis was conducted using the R packages “survminer” and “survival” to examine differential survival outcomes between the two groups.

Correlation Analysis of OAS3 Expression With Microsatellite Instability and Tumour Mutational Burden

Tumour mutational burden (TMB) is defined as the total number of mutations per million bases in the coding region of the exons of genes encoding specific tumour cell proteins, including insertions, substitutions, deletions, and other forms of mutations (Alexandrov et al., 2013). It is also an emerging biomarker for tumour immunotherapy prediction and may help to predict the benefits of immunotherapy in certain tumours. Microsatellite instability (MSI) is characterised by a genetic change. During the proliferation of normal cells, an intact DNA mismatch repair (MMR) system detects replication errors in microsatellite sequences in a timely manner and corrects them quickly so that the sequences are replicated with high fidelity, thus maintaining microsatellite stability. Owing to defective DNA MMR during tumorigenesis in certain tumours, errors in microsatellite sequence replication cannot be detected promptly, leading to the insertion or deletion of repetitive units and changes in microsatellite sequence length, eventually

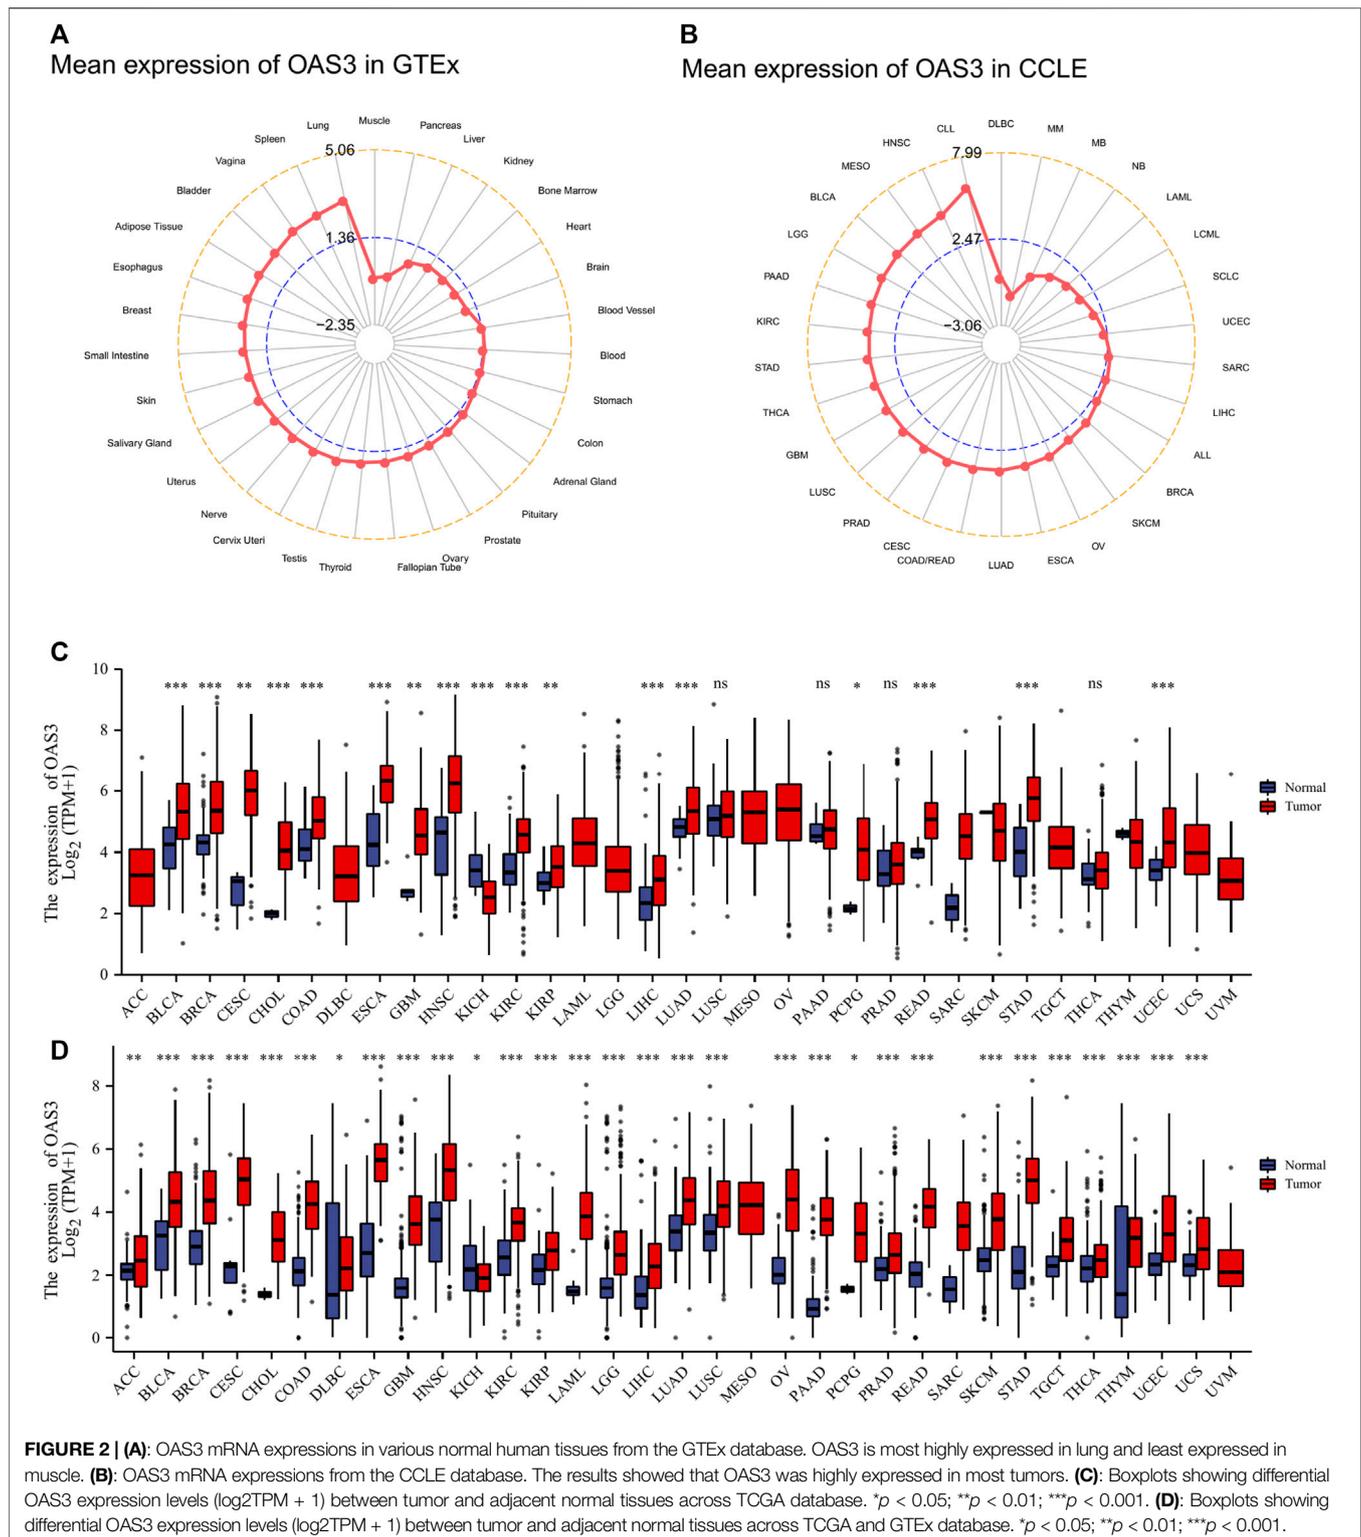

leading to MSI (Ellegren, 2004). Several clinical trials, retrospective studies and meta-analyses have confirmed that MSI is strongly associated with tumour prognosis (Petrelli et al., 2019). In this study, gene mutation data of 33 cancer types were obtained from TCGA database of UCSC Xena. TMB was calculated for each sample using R. The correlation of OAS3 expression with TMB and MSI was analysed via Spearman’s correlation test, and the R package “fmsb” was used to visualise the results.

Correlation Analysis of OAS3 Expression With TME

TME is critical for the regulation of cancer development and therapy (Zhou et al., 2019). It contains stromal, tumour, and immune cells (Luo and Vögeli, 2020). The number of stromal and immune cells in TME affects many aspects of cancer growth and development. The “ESTIMATE” R package was used to assess immune infiltration (based on the ImmuneScore, StromalScore, and ESTIMATEScore) using the transcriptome data (Chen et al., 2021a). Subsequently, we analysed the association between OAS3 and TME using R.

Analysis of Tumour Immune Cell Infiltration

We used TIMER2, Xcell, CIBERSORT, and ImmuCellAI to analyse the correlation between OAS3 expression and infiltration of various immune cell types. The TIMER2 database contains information on 32 cancers and 10,897 tissues from TCGA database, which allows systematic analysis of the correlation between one or more tumours and immune cell infiltration as well as the correlation between the expression of relevant genes in tumour tissues and the prognosis, mutation and copy number of patients (Ju et al., 2020). ImmuCellAI ([Frontiers in Cell and Developmental Biology | \[www.frontiersin.org\]\(http://www.frontiersin.org\)](http://</p>
</div>
<div data-bbox=)

bioinfo.life.hust.edu.cn/web/ImmuCellAI/) is a powerful and unique method for accurately screening tumour immune function using 24 different types of immune cells, including T cells (Huang et al., 2021). Furthermore, the XCell algorithm was used to examine several features of tumours, including the

composition of infiltrating immune cells, based on the gene expression data (Schulze et al., 2020). In addition, the CIBERSORT algorithm was used to identify immune cell infiltration signatures using the R package “cibersort” (Wu et al., 2020).

Correlation of OAS3 Expression With Immune Checkpoint-Related Genes and Immune Neoantigens

Immune checkpoints refer to a subset of inhibitory signalling pathways involved in the immune response (Yuan et al., 2020). Abnormal expression of immune checkpoint-related genes is associated with tumorigenesis (Liu et al., 2021a). We examined the association of OAS3 with 47 immune checkpoint-associated genes in 33 cancers using Pearson correlation analysis. Neoantigens are abnormal proteins derived from “nonsynonymous mutations” from biological events such as point mutations, deletion mutations, and gene fusions and are specific to tumour cells (Liao and Zhang, 2021; Xu et al., 2021). The immune activity of tumour neoantigens can be used to design and synthesise neoantigen vaccines according to the conditions of the bulge of the swollen cell; these vaccines can be used to immunise patients to achieve therapeutic effects (Chen et al., 2021b). We counted the number of neoantigens in each tumour sample and used Spearman’s correlation test to investigate the relationship between OAS3 and the number of antigens.

Correlation of OAS3 Expression With the Expression of DNA MMR Genes, RNA Methylation-Related Genes and DNA Methyltransferase

MMR is a critical post-replicative DNA repair process, which is essential for maintaining genomic integrity (Popp and Bohlander, 2010). Defects in the MMR system lead to genetic instability referred to as MSI (Alhopuro et al., 2012). DNA methylation is a chemical modification of DNA that can change genetic performance without changing the DNA sequence (Alhopuro et al., 2012). RNA methylation is one of the most important post-transcriptional epigenetic RNA modifications (Tian et al., 2021). The most commonly used RNA modifications are m6A, m1A, and m5C, which play a key role in the progression of cancers, including growth and invasion (Mcelhinney et al., 2020). In this study, we examined the relationship between OAS3 expression and the abovementioned genes using the R package “RColorBrewer”.

Correlation of OAS3 Expression With Drug Sensitivity

The relationship between OAS3 and IC50 of drugs was analysed based on the GDSC2 data. In addition, we compared the drug sensitivity of the OAS family using the Cancer Therapeutics Response Portal 21 (CTRP, <http://portals.broadinstitute.org/ctrp/>). The likelihood of an immunotherapy response was estimated using the TIDE algorithm (Khanna et al., 2019; Yang et al., 2020).

Quantitative Real-Time PCR

Total RNA was extracted from the target tissue samples and thoroughly ground in a mortar under liquid nitrogen. To lyse the cells, 1 ml of Trizol reagent (Life Technology, Grand Island, NY, United States) was added and the sample was incubated for 15 min at room temperature on a shaker. To assess the mRNA expression

level, the RevertAid First Strand cDNA Synthesis Kit (Thermo Scientific, Lithuania) was used to synthesis the first-strand cDNA. Quantitative PCR was performed using Roche LightCycler® 480 Real-Time PCR System with SYBR® Green qPCR mix 2.0 kit. The primers used in this study were obtained from TsingKe biological technology (Nanjing, China), including OAS3 (forward 5'-CAC CGGCGATGCCCGCATCTCACTG -3', reverse 5'-AAACCA GTGAGATGCGGGCATCGCC-3'). The relative mRNA levels were calculated by the 2- $\Delta\Delta$ Ct method.

Western Blot

Western blot was performed to determine the protein expression level. The protein samples were denatured for 5 min at 95°C in a sample buffer and separated by SDS-PAGE. Western blot analysis was performed using antibodies against mouse monoclonal antibody-anti-human OAS3, and mouse monoclonal antibody-anti-human β -actin (Santa Cruz Biotechnology), followed by incubation with horseradish peroxidase (HRP)-coupled mouse secondary antibody (1:10,000). The blots were re-probed with a β -actin antibody (BD Bioscience, United States), and the signals were quantified using an image analyzer (UVtec, United Kingdom). The data were shown as percentages of the normalized control signal.

RESULTS

Expression Levels of OAS3 in Various Normal and Cancerous Tissues

Data from the GTEx database showed that OAS3 was abundantly expressed in various normal tissues, with the highest and lowest expression observed in the lung and muscle, respectively (Figure 2A). In addition, the expression of OAS3 was higher in various cancer cell lines in the Cancer Cell Line Encyclopedia (CCLE) database than in normal tissue (Figure 2B). In TCGA data, differences in OAS3 expression were significant among 17 of the 33 cancer types analysed (except for KICH, in which OAS3 expression was lower than that in most tumour tissues) (Figure 2C). However, when the GTEx and TCGA data were combined, the difference was significant among 29 of the 33 cancers, and OAS3 expression was lower in KICH than in normal tissues (Figure 2D). To investigate the intracellular localisation of OAS3, we assessed the distribution of OAS3 in the endoplasmic reticulum (ER) and microtubules of A431, A549, and U-2 osteosarcoma (OS) cells using an indirect immunofluorescence assay. We observed that OAS3 colocalised with ER and microtubule markers in A431, A549 and U-2 OS cells, suggesting the subcellular localisation of OAS3 in ER and microtubules. However, OAS3 exhibited no overlap with the nucleus of A431, A549, and U-2 OS cells (Supplementary Figure S1).

Relationship of OAS3 With Clinical Staging and Prognosis

We examined the relationship between OAS3 expression and different tumour stages and found that DLBC, HNSC, KIRC, LIHC, LUSC, MESO, OV, PAAD, LUAD, SKCM, and UCS were

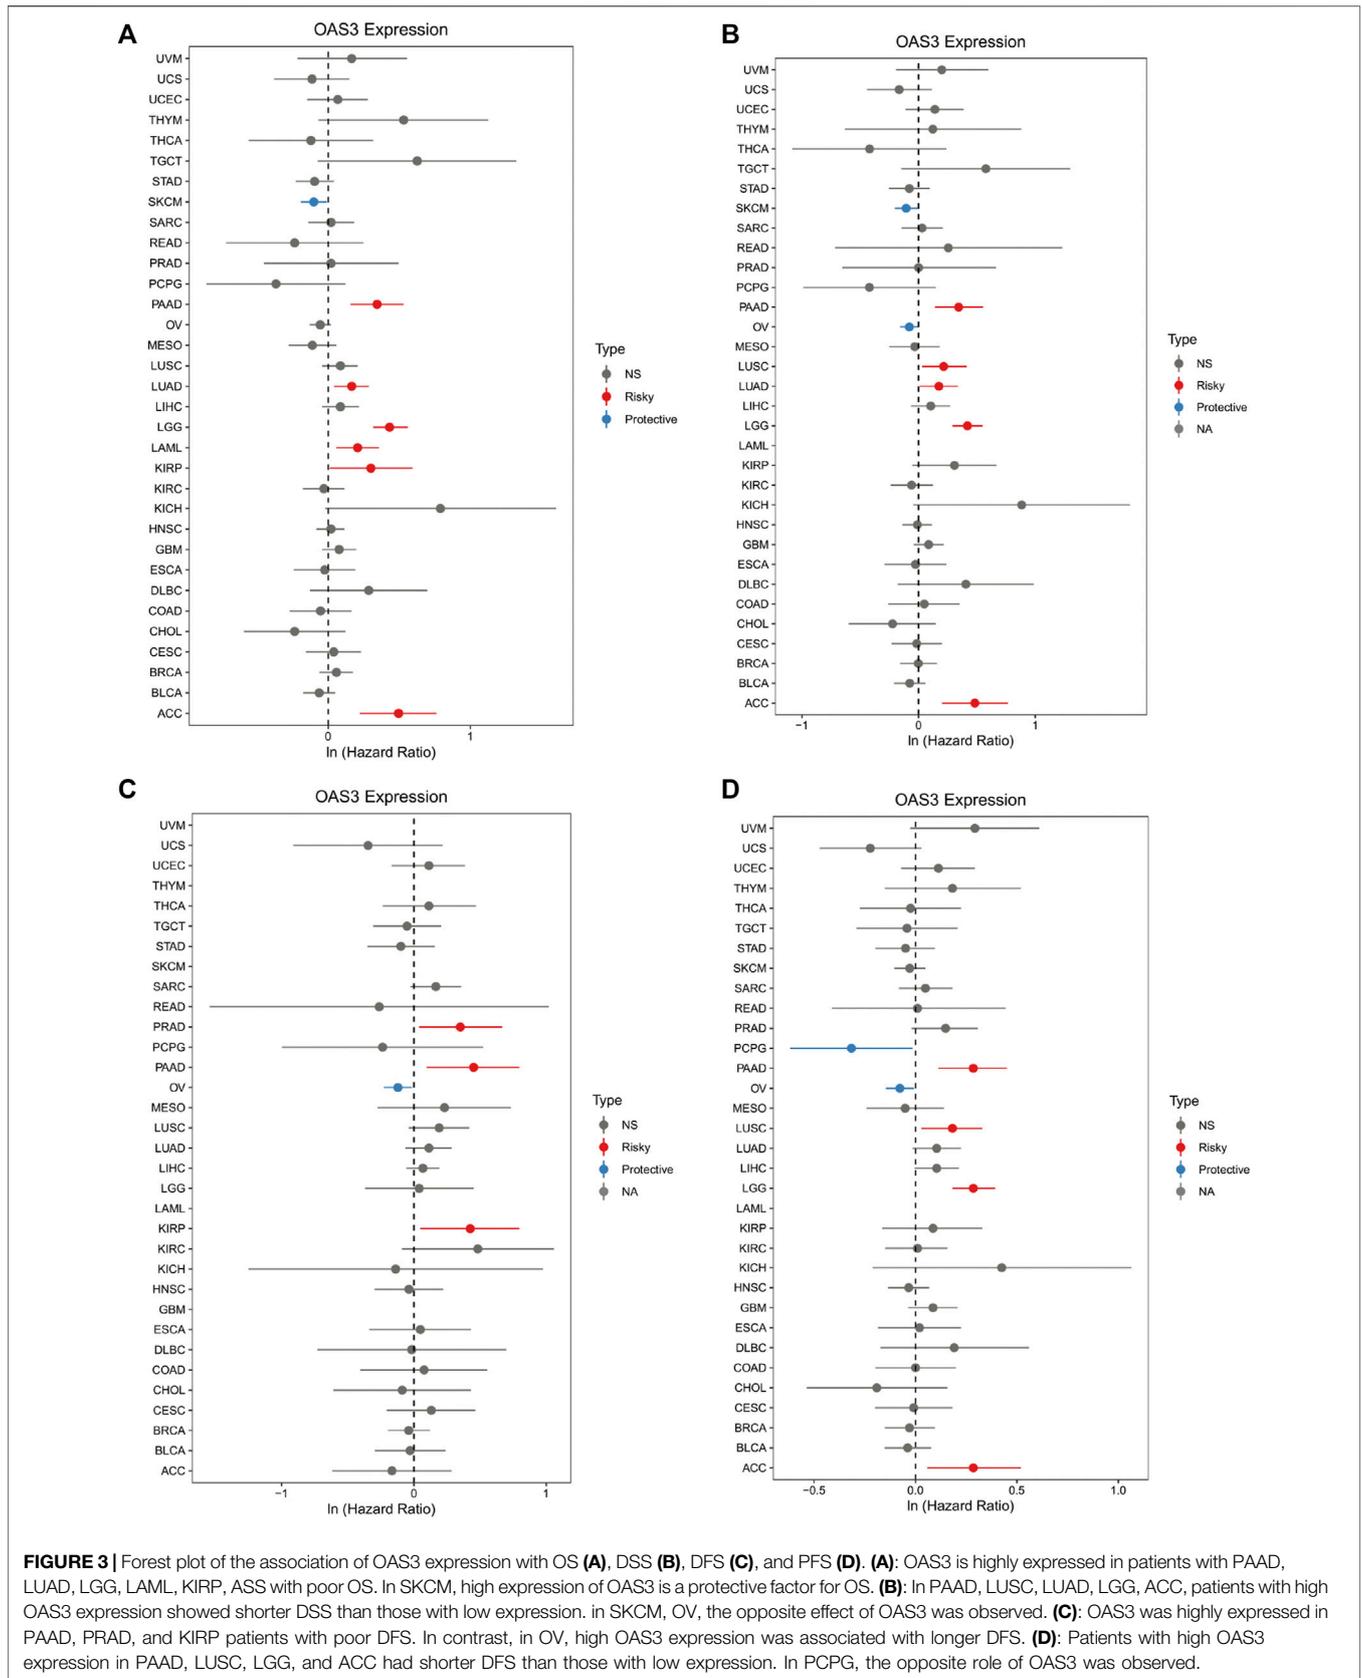

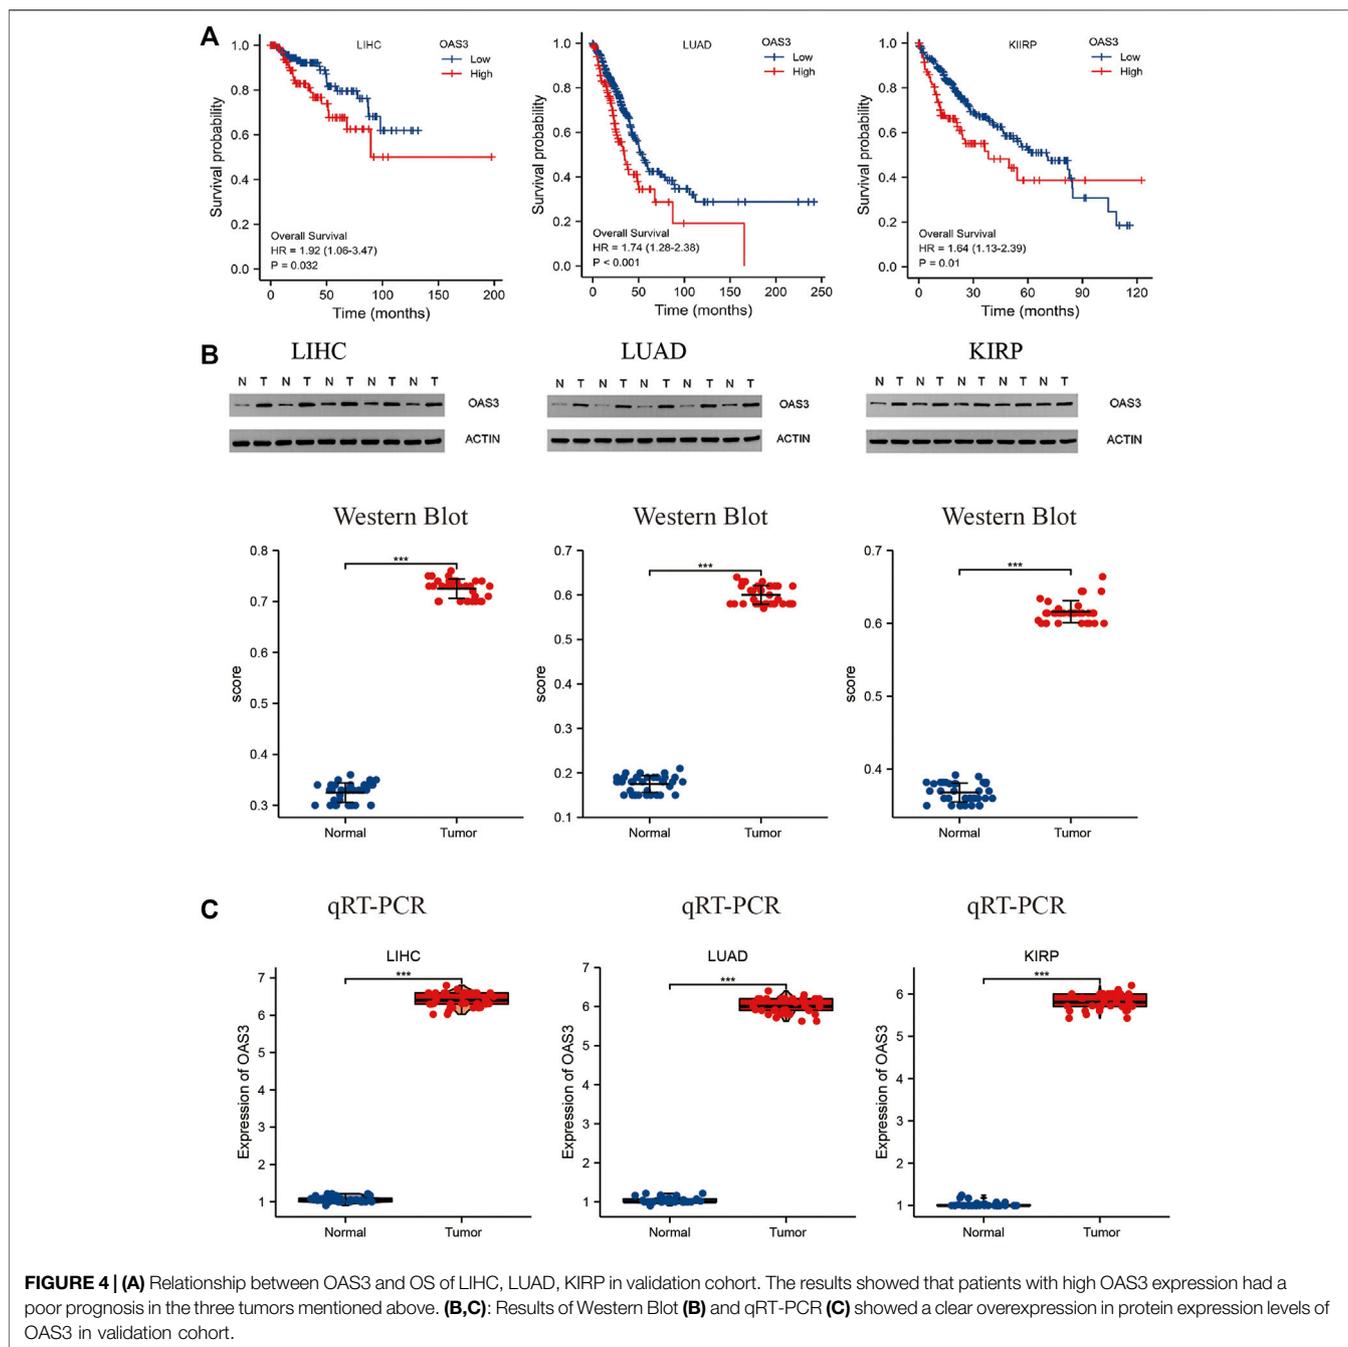

FIGURE 3 | Forest plot of the association of OAS3 expression with OS (A), DSS (B), DFS (C), and PFS (D). (A): OAS3 is highly expressed in patients with PAAD, LUAD, LGG, LAML, KIRP, ASS with poor OS. In SKCM, high expression of OAS3 is a protective factor for OS. (B): In PAAD, LUSC, LUAD, LGG, ACC, patients with high OAS3 expression showed shorter DSS than those with low expression. In SKCM, OV, the opposite effect of OAS3 was observed. (C): OAS3 was highly expressed in PAAD, PRAD, and KIRP patients with poor DFS. In contrast, in OV, high OAS3 expression was associated with longer DFS. (D): Patients with high OAS3 expression in PAAD, LUSC, LGG, and ACC had shorter DFS than those with low expression. In PCPG, the opposite role of OAS3 was observed.

positively correlated with the expression of *OAS3*. This finding suggests that *OAS3* plays an important role in tumorigenesis (**Supplementary Figure S2**). Furthermore, we investigated the relationship between *OAS3* expression and the prognosis of 33 cancers. According to the Cox proportional hazards model, *OAS3* expression was positively correlated with OS in patients with PAAD, LUAD, LGG, LAML, KIRP, and ACC and negatively correlated with OS in patients with SKCM (**Figure 3A**). In addition, we analysed the DSS data and found a positive correlation between *OAS3* expression and prognosis in patients with PAAD, LUSC, LUAD, LGG, and ACC. However,

OAS3 expression was negatively correlated with the prognosis of SKCM and OV (**Figure 3B**). Based on the correlation between *OAS3* expression and DFS, we identified *OAS3* as a prognostic risk factor for PRAD, PAAD, and KIRP but as a protective factor for OV (**Figure 3C**). Similarly, high *OAS3* expression was associated with worse PFS in PAAD, LUSC, LGG, and ACC (**Figure 3D**). Furthermore, Kaplan–Meier analysis showed that high *OAS3* expression was associated with worse OS in ACC, DLBC, KICH, KIRP, LAML, LGG, LUAD, and PAAD but with better OS in MESO (**Supplementary Figure S3**). High *OAS3* expression was correlated with worse DFS in four types of

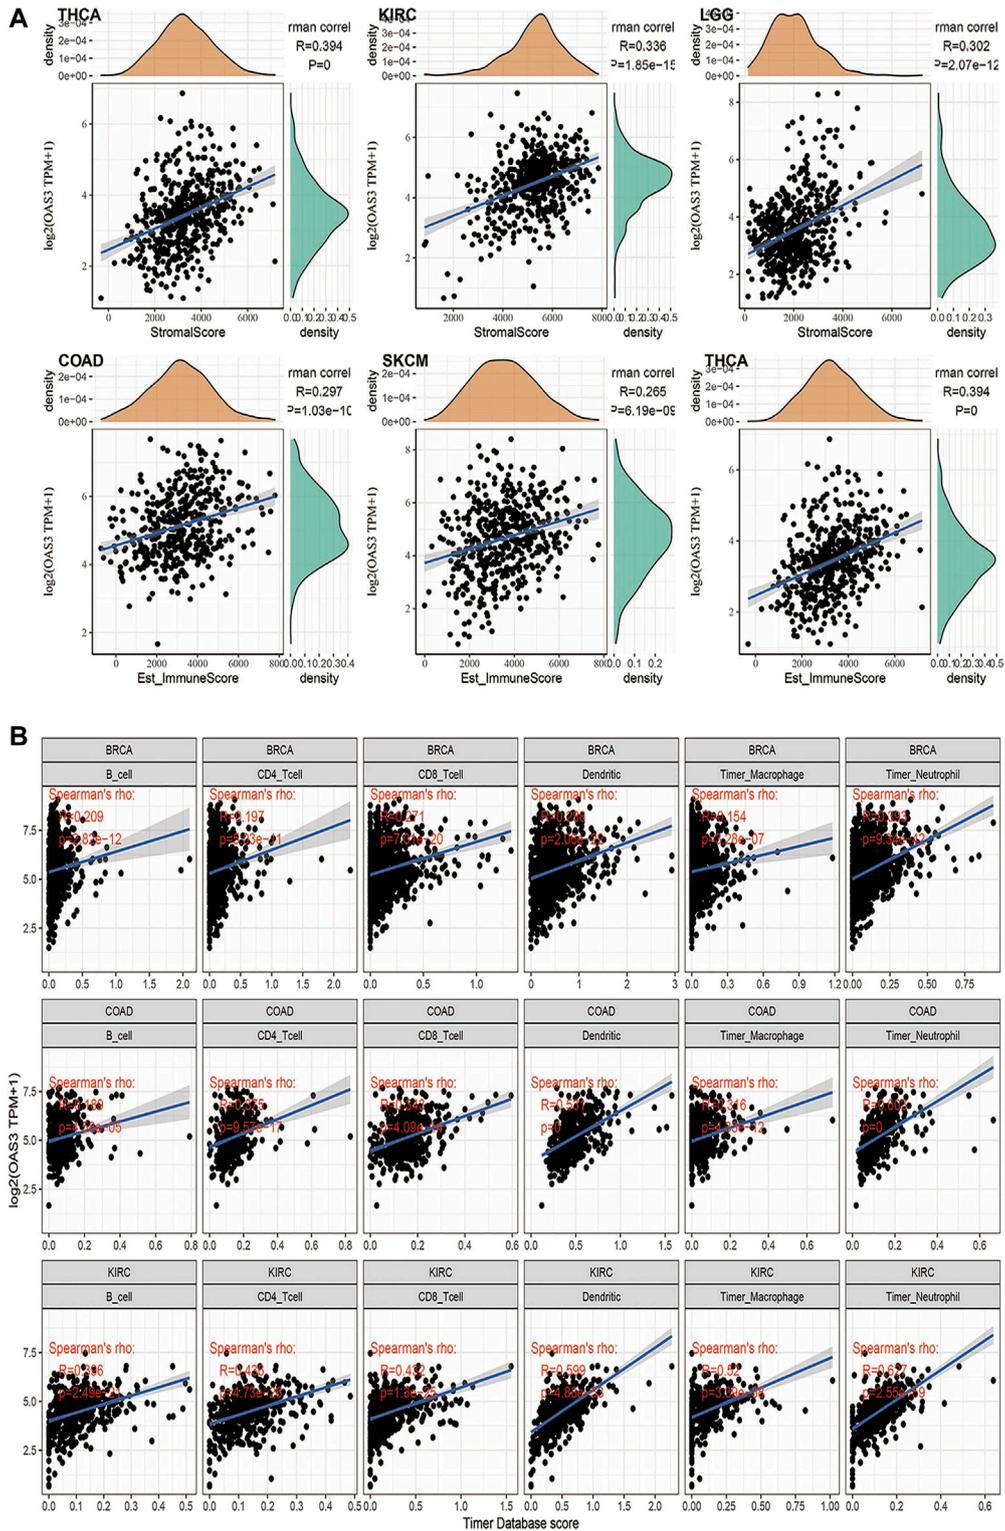

FIGURE 5 | (A) Among the 33 tumors, the top 3 tumors with the highest stromal scores were THCA, KIRC, LGG; the highest immune scores were COAD, SKCM, THCA; the highest ESTIMATEScore was COAD, SKCM, THCA. **(B)** TIMER analyzed relationship between OAS3 expression and the abundance of tumor-infiltrating immune cells in BRCA, COAD, KIRC. The results showed a positive correlation between OAS3 expression and immune cell infiltration.

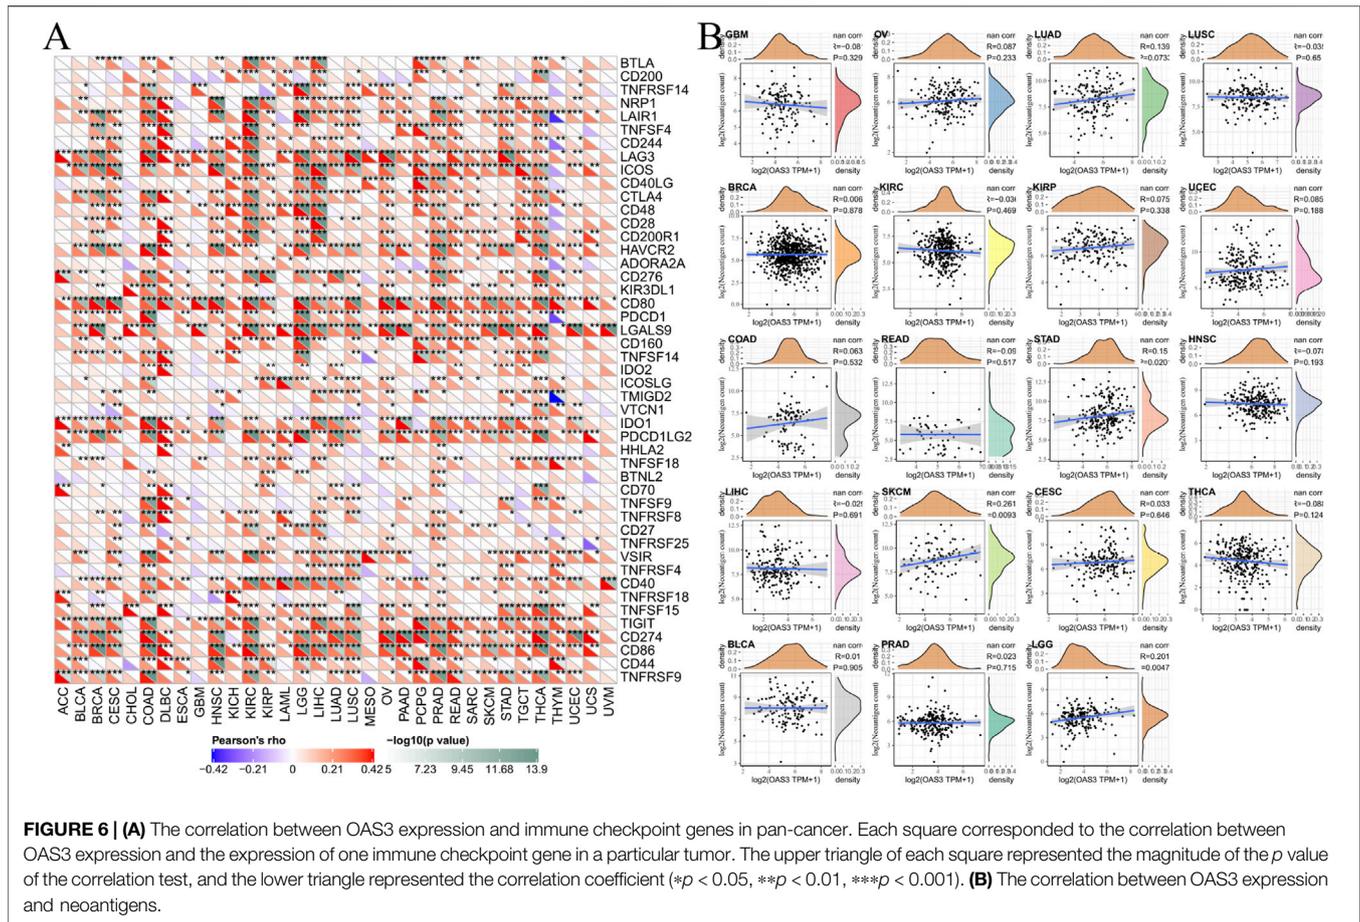

FIGURE 6 | (A) The correlation between OAS3 expression and immune checkpoint genes in pan-cancer. Each square corresponded to the correlation between OAS3 expression and the expression of one immune checkpoint gene in a particular tumor. The upper triangle of each square represented the magnitude of the p value of the correlation test, and the lower triangle represented the correlation coefficient ($*p < 0.05$, $**p < 0.01$, $***p < 0.001$). **(B)** The correlation between OAS3 expression and neoantigens.

tumours, including KIRP and PAAD (Supplementary Figure S4). In seven types of tumours, including ACC and DLBC, patients with high OAS3 expression had worse DSS (Supplementary Figure S5). These findings suggest that OAS3 is an oncogene that is associated with tumour progression, can help to predict survival in patients with various tumours and is a potential biomarker for tumour prognosis, especially for the prognosis of PAAD, LUAD, KIRP, and UVM.

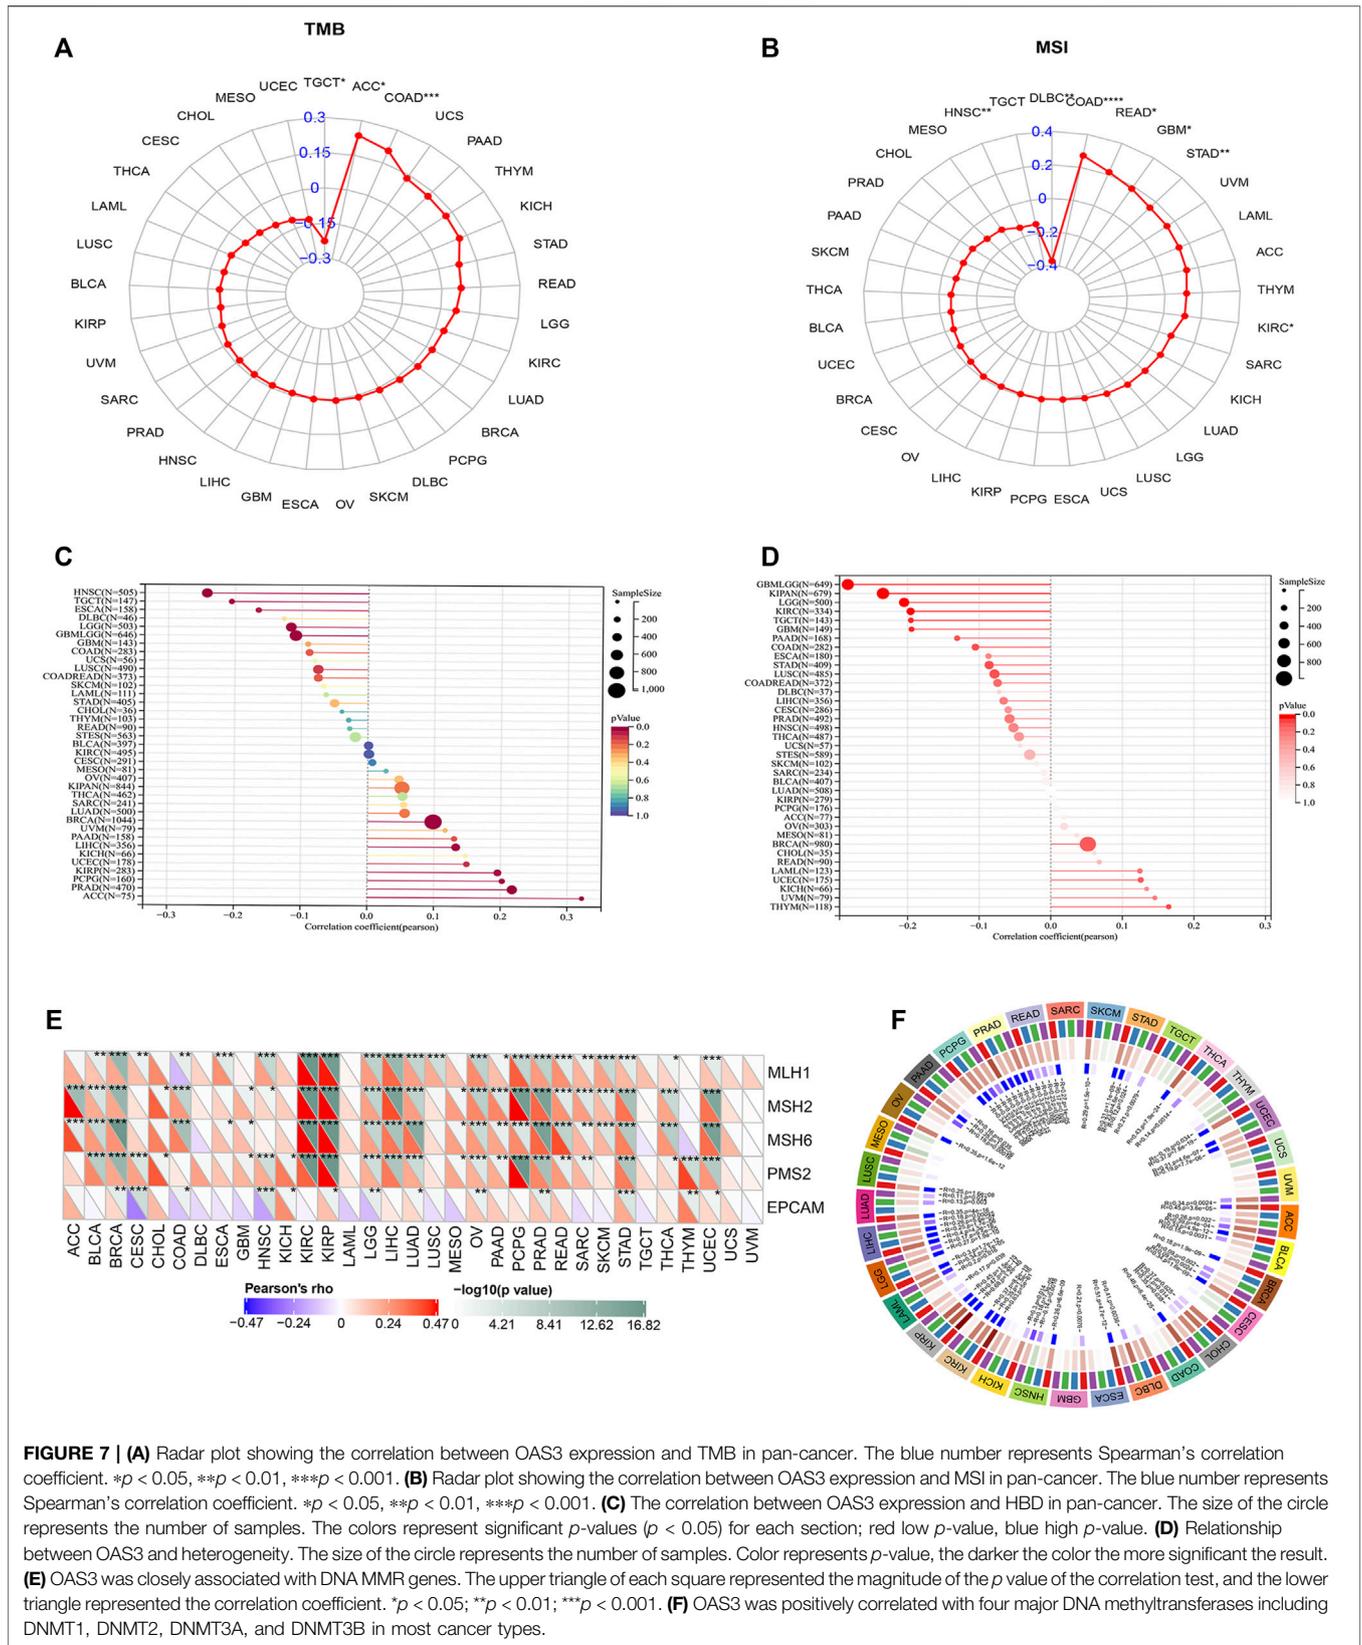

Validation of the Expression and Prognostic Role of OAS3

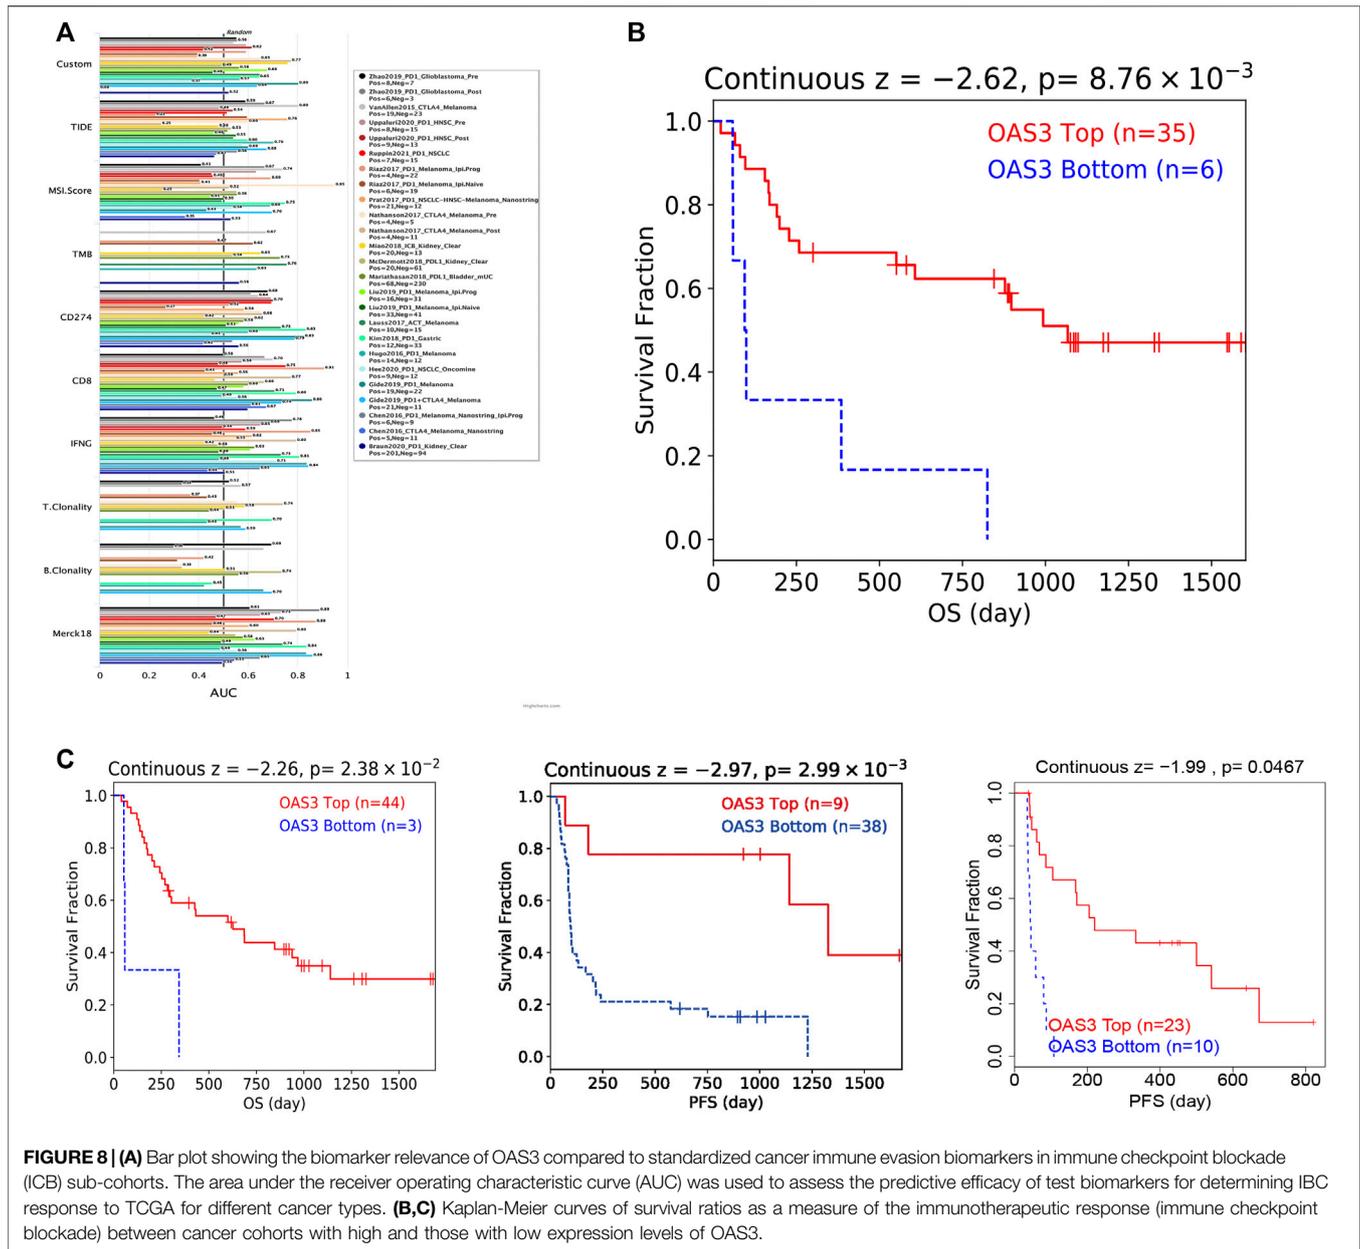

To substantiate the conclusion of the data analysis, we validated OAS3 expression in 36 patients with LIHC, 30 patients with LUAD and 30 patients with KIRP and performed survival analysis in conjunction with clinical trials. As shown in Figure 4A, patients with high OAS3 expression in the validation group had a poorer prognosis in patients with LUAD, KIRP; this is consistent with our findings in the TCGA cohort. Also, we found a poorer prognosis for patients with high OAS3 expression in LIHC in the validation group. Meanwhile, OAS3 was detected using qRT-PCR and western blotting. The results of western blotting was consistent with those of qRT-PCR: OAS3 was highly expressed in tumor tissues in

LIHC, LUAD, KIRP, and low in normal tissues (Figures 4B, C). TCGA cohort results are mostly consistent with our findings. This ensured breadth and thereby enhanced credibility in the data.

Correlation of OAS3 With TME and Immune-Infiltrating Cells

We evaluated the correlation between OAS3 and immune and stromal scores. As shown in Supplementary Figure S6, immune scores, ESTIMATEScore and stromal scores were significantly correlated with OAS3 expression in 20, 25, and 20 of the 33 cancers, respectively. Figure 5A shows the top three significant genes in each score, with COAD having the highest immune score and ESTIMATEScore and THCA having the highest substrate score. The results showed that OAS3 expression strongly correlates with the degree of immune infiltration in different cancer types. Therefore, we investigated the relationship between OAS3 and immune infiltrating cells in 33 cancer types using the TIMER database. The top three significant cell types are shown in Figure 5B, demonstrating that OAS3 correlates significantly with tumor purity and with six types of immunoinfiltrated cells, including CD8⁺ T cells, CD4⁺ T cells, B cells, dendritic cells, and macrophages in KIRC, COAD and BRCA. Based on the

results of immune analysis, OAS3 was related to poor prognosis in some tumours and might affect immune activities. Therefore, we examined the correlation between OAS3 and immune-related cells using Xcell, TIMER2, CIBERSORT and ImmuCellAI to validate the results and found that OAS3 was significantly correlated with neutrophils and macrophages (Supplementary Figures S7A–C). In addition, cancer-associated fibroblasts, a type of immunosuppressive cells, had a strong positive correlation with OAS3 expression. The data from the ImmuCellAI database further suggested a significant positive correlation between OAS3 and the immunosuppressive cells iTregs and nTregs (Supplementary Figure S7D). Therefore, OAS3 may affect tumour progression through macrophages, iTregs, CAFs, and other immune cells.

Correlation of OAS3 Expression With Immune Checkpoint Genes and the Number of Immune Neoantigens Implicates OAS3 in the Tumour Immune Response

The correlation between OAS3 expression and 47 immune checkpoint genes in pan-cancer is shown in Figure 6A. In diverse cancer types, the correlation between OAS3 and the expression of checkpoint genes indicated a high correlation with TNF-related immune genes including TNFRSF14, TNFRSF8, TNFRSF25, TNFRSF4, TNFRSF18, TNFRSF15, and TNFRSF9. The expression of OAS3 was positively correlated with that of immune checkpoint-related genes in most tumours, suggesting that OAS3 is involved in the

regulation of tumour immune response through the regulation of immune checkpoint activity. Therefore, *OAS3* may provide some help for tumour immunotherapy, thus facilitating the spread of tumours. The correlation between *OAS3* expression and neoantigens is shown in **Figure 6B**. A significant positive correlation was found between *OAS3* expression and the number of neoantigens in LGG, SKCM, and STAD.

OAS3 Expression Was Significantly Correlated With TMB and MSI

We obtained *OAS3* mutation data of various tumours from the UCSC Xena database. *OAS3* mRNA was found to be significantly mutated in TGCT, ACC, COAD, and other tumours (**Figure 7A**), suggesting that mutated *OAS3* plays a key role in promoting the development of these tumours (**Figure 7B**). HRD produces specific, quantifiable, and stable genomic alterations, and the HRD status is a key indicator of treatment choice and prognosis in various tumours. Clinical studies have confirmed that the HRD status is highly correlated with sensitivity to platinum-based chemotherapeutic agents and PARP inhibitors (Min et al., 2020). We found that *OAS3* was positively correlated with HRD in ACC, PRAD, and KIRP (**Figure 7C**), and the heterogeneity of THYM, UVM, and KICH increases with an increase in *OAS3* expression (**Figure 7D**).

Coexpression of OAS3 With Some Specific Genes

Based on the association between *OAS3* expression and the mutational markers TMB and MSI, the relationship between *OAS3* expression and oncogenic processes was further investigated. We found that *OAS3* was closely associated with DNA MMR genes, showing a positive correlation with MLH1, MSH2, MSH6, and PMS2 and a negative correlation with EPCAM in most tumours (**Figure 7E**). In addition, *OAS3* was positively correlated with four major DNA methyltransferases including DNMT1, DNMT2, DNMT3A, and DNMT3B in most cancer types (**Figure 7F**). RNA methylation is a post-transcriptional modification that widely exists in eukaryotes and prokaryotes. We found that *OAS3* had a significant positive correlation with RNA methylation-related genes (m1A, m5C, and m6A) in most tumours (**Supplementary Figure S8A**). In addition, a positive correlation was found between *OAS3* and four immune pathway-related genes [receptor (Chen et al., 2021a), MHC (Schulze et al., 2020), immunoinhibitors (Liu et al., 2021a) and immunostimulators^[46]] in many tumour types (**Supplementary Figure S8B**).

Analysis of Drug Sensitivity

We analysed 198 drugs and found that *OAS3* shared the most evident positive correlation with BI-2536, GSK269962A, vorinostat, sorafenib, BMS-754807, and nutlin-3a (–), indicating that high *OAS3* expression may lead to drug resistance. *OAS3* had the strongest negative correlation with trametinib, sapitinib, SCH772984, selumetinib, and dasatinib (**Supplementary Figure S9A**). A bubble plot demonstrating

the correlation between the sensitivity of drugs in the CTRP database and mRNA expression of *OAS3* is shown in **Supplementary Figure S9B**.

OAS3 Was Correlated With Immunotherapeutic Responses

We assessed the reliability of *OAS3* as a biomarker by comparing it with standardised biomarkers for predicting response and OS in the IBC subpopulation. We found that the area under the receiver operating characteristic curve (AUC) of *OAS3* alone was greater than 0.5 in 16 of 23 IBC subgroups (**Figure 8A**), and that the predictive value of *OAS3* alone was higher than that of TMB, T. clonalum, and B. clonalum. However, the predictive ability of *OAS3* was similar to that of IFGN (AUC>0.5 for 17 ICD subgroups), but lower than that of CD274, TIDE and Merk18. In addition, the results demonstrated that high expression levels of *OAS3* were associated with better PD1 OS in melanoma (Gide2019_PD1, Liu2019_PD1) and better PFS in kidney renal clear cell carcinoma and melanoma (Miao2018_ICB, Liu2019_PD1) (**Figures 8B, C**).

Pathway Analysis

We performed Spearman correlation analysis on *OAS3* and pathway scores. A close association was observed between *OAS3* and pathways including tumour inflammation signature, cellular response to hypoxia, tumour proliferation signature, angiogenesis, and apoptosis. The higher the expression of *OAS3*, the stronger the activity of the related pathway (**Supplementary Figure S10**).

DISCUSSION

The molecular mechanisms underlying the role of *OAS3* in the immune microenvironment and pathogenesis of different tumours remain unknown. In this study, we performed an integrative analysis of molecular characteristics, oncogenic roles and relevant immune and pharmacogenomic features of *OAS3* in pan-cancer. The findings suggest that *OAS3* is closely associated with the development of various systemic diseases and cancers. In addition, a functional association was observed between *OAS3* and TME, especially immunosuppressive cells.

We compared the expression of *OAS3* in normal and tumour tissues of 33 cancers and found that *OAS3* was dysregulated and highly expressed in almost all TCGA tumour types and was associated with the staging or metastasis of DLBC, HNSC, KIRC, LIHC, LUSC, MESO, OV, PAAD, LUAD, SKCM, and UCS. These findings suggest that *OAS3* is an important regulator of carcinogenesis, progression, invasion and metastasis in various cancers. Regarding the prognostic value of *OAS3* in pan-cancer, we observed that *OAS3* was closely associated with survival indicators such as OS, DSS, DFS, and PFS, and high *OAS3* expression was associated with poorer survival rates in CESC, GBM, KICH, KIRP, LAML, LGG, LIHC, LUAD, LUSC, PAAD, TGCT, and ACC. In previous studies, *OAS3* has been reported as a risk factor for different cancers, which is consistent with the

results of this study (Piera-Velazquez et al., 2021; Calvet et al., 2022; Shi et al., 2022).

TME is closely associated with tumour growth, progression and prognosis and immune cells play an important role in tumour growth and progression (Lei et al., 2021). Previous studies have found that cytokines in TME regulate immune function and eventually suppress the immune response, leading to tumour progression (Hinshaw and Shevde, 2019). Therefore, analysing the components of TME can help to develop drugs for targeted tumour immunotherapy. In this study, a significant positive correlation was observed between *OAS3* and the immunosuppressive cells iTregs and nTregs. Immune checkpoint inhibitors are effective anti-cancer immunotherapeutic approaches (Li et al., 2019). In this study, *OAS3* expression was positively correlated with 47 immune checkpoint genes in most cancer types. Therefore, *OAS3* can be used as a novel drug target for anti-cancer immunotherapy.

Furthermore, we analysed the correlation between the expression of *OAS3* and MMR-related genes, RNA methylation genes and four DNA methyltransferases. MMR can repair errors that occur during DNA replication (Vilar and Gruber, 2010) and is known to repair microsatellite replication errors. However, defects in MMR (dMMR) can lead to MSI (Jiricny, 2006). RNA methylation plays a crucial role in the tumorigenesis and progression of tumours (Chen et al., 2020). Altered DNA methylation is also associated with tumorigenesis (Kulis and Esteller, 2010). Based on the findings of this study, *OAS3* expression is positively correlated with MMR-related genes, RNA methylation and four DNA methyltransferases in most cancers. Altogether, the findings demonstrate that *OAS3* mediates tumorigenesis by regulating DNA damage and DNA and RNA methylation.

Based on the abovementioned results, *OAS3* may serve as a very important biomarker for tumour immunotherapy. Monoclonal antibodies-targeting CTLA-4, PD-1 or PDL-1 have shown clinical potential for effectively controlling and treating human cancers (Liu et al., 2021b). This study showed that patients with melanoma and kidney renal clear cell carcinoma with high *OAS3* expression had a higher clinical benefit from ICB treatment (PD-1 or PD-L1). On analysing the relationship between *OAS3* and the IC50 of drugs using the GDSC2 database, we found that high *OAS3* expression might lead to resistance to BI-2536, GSK269962A, vorinostat, sorafenib, and BMS-754807. However, high *OAS3* expression was negatively correlated with trametinib, sapitinib, SCH772984, selumetinib, and dasatinib. This finding provides a basis for selecting anti-tumour agents for patients in the future.

CONCLUSION

This study showed that *OAS3* is highly expressed in various tumours, and high *OAS3* expression is associated with poor survival outcomes. In addition, we demonstrated the association between *OAS3* and the expression of immune-

infiltrating cells, immune checkpoint genes, TMB, and MSI. *OAS3* may influence tumour progression through immunosuppression. The evidence for the significant immunological utility of *OAS3* as a prognostic and immunotherapeutic biomarker for pan-cancer provides compelling new insights into the potential development of future immunotherapeutic and diagnostic trials. Therefore, the findings of this study will contribute to the development of new therapeutic approaches for patients with cancer, improving their treatment and prognosis.

DATA AVAILABILITY STATEMENT

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found in the article/**Supplementary Material**.

ETHICS STATEMENT

The studies involving human participants were reviewed and approved by the Committees for Ethical Review of Research of The First Affiliated Hospital of Zhengzhou University and Jiading District Central Hospital Affiliated Shanghai University of Medicine. Written informed consent to participate in this study was provided by the participants or their legal guardian/next of kin.

AUTHOR CONTRIBUTIONS

Xi-tao Yang, Xin-yu Li, Lei Hou, Lu-yu Zhang carried out experiments; Xin-yu Li, Lei Hou, Lu-yu Zhang, Liming Zhang, Deming Wang, Zhenfeng Wang, Ming-Zhe Wen wrote the manuscript, Xi-tao Yang performed manuscript review.

FUNDING

This study received Fundamental research program funding of Ninth People's Hospital affiliated to Shanghai Jiao Tong university School of Medicine (No. JYZZ076), Clinical Research Program of Ninth People's Hospital, Shanghai Jiao Tong University School of Medicine (No. JYLJ201801, JYLJ201911), the China Postdoctoral Science Foundation (No. 2017M611585), and the National Natural Science Foundation of China (No. 81871458).

ACKNOWLEDGMENTS

We gratefully acknowledge the Home for Researchers editorial team (www.home-for-researchers.com). Thanks to Figdraw ([www.figdraw](http://www.figdraw.com)) for technical support. We thank Dr. Jianxiong You, Department of Interventional Therapy, Ninth People's

Hospital, Shanghai Jiao Tong University Medical College, for providing the samples.

SUPPLEMENTARY MATERIAL

The Supplementary Material for this article can be found online at: <https://www.frontiersin.org/articles/10.3389/fcell.2022.815480/full#supplementary-material>

Supplementary Figure 1 | Immunofluorescence staining of the subcellular distribution of OAS3 from the HPA database. We observed that OAS3 colocalised with ER and microtubule markers in A431, A549, and U-2 OS cells, suggesting the subcellular localisation of OAS3 in ER and microtubules.

Supplementary Figure 2 | Boxplots showing differential OAS3 expression levels (log2 TPM + 1) between pathological stages and DLBC, HNSC, KIRC, LIHC, LUSC, MESO, OV, PAAD, LUAD, SKCM, and UCS were positively correlated with the expression of OAS3. This finding suggests that OAS3 plays an important role in tumorigenesis. Only TCGA cancers with statistically significant differences between the pathological stages are presented.

Supplementary Figure 3 | Kaplan-Meier analysis for OS according to OAS3 expression. Only statistically significant cancers (p -value < 0.05) are listed.

Supplementary Figure 4 | Kaplan-Meier analysis for DFS according to OAS3 expression. Only statistically significant cancers (p -value < 0.05) are listed.

Supplementary Figure 5 | Kaplan-Meier analysis for DSS according to OAS3 expression. Only statistically significant cancers (p -value < 0.05) are listed.

Supplementary Figure 6 | The correlation between OAS3 and immune scores (A), ESTIMATEScore (B), and stromal scores (C) in pancreatic.

Supplementary Figure 7 | Four methods were used to calculate the correlation between OAS3 and immune-related cells. Xcell (A), TIMER2 (B), CIBERSORT (C), and ImmuCellAI (D). The lower upper triangle of each square represented the magnitude of the p value of the correlation test, and the upper triangle represented the correlation coefficient ($*p < 0.05$, $**p < 0.01$, $***p < 0.001$).

Supplementary Figure 8 | (A) OAS3 had a significant positive correlation with RNA methylation-related genes (m1A, m5C, and m6A) in most tumours. The lower upper triangle of each square represented the magnitude of the p value of the correlation test, and the upper triangle represented the correlation coefficient ($*p < 0.05$, $**p < 0.01$, $***p < 0.001$). (B) A positive correlation was found between OAS3 and four immune pathway-related genes (receptor, MHC, immunoinhibitors, and immunostimulators) in many tumour types. The lower upper triangle of each square represented the magnitude of the p value of the correlation test, and the upper triangle represented the correlation coefficient ($*p < 0.05$, $**p < 0.01$, $***p < 0.001$).

Supplementary Figure 9 | The correlation between the sensitivity of drugs in the Genomic of Drug Sensitivity in Cancer (GDSC) database (A), CTRP database (B), and mRNA expression of OAS3. The Pearson's correlation indicates the correlation between gene expression and drugs sensitivity. Blue bubbles represented negative correlations, and red bubbles represented positive correlations; the deeper the color, the higher the correlation. The bubble size was positively correlated with the FDR significance.

Supplementary Figure 10 | Pathway analysis. The abscissa represents the distribution of the gene expression, and the ordinate represents the distribution of the pathway score. The density curve on the right represents the trend in distribution of pathway immune score, the upper density curve represents the trend in distribution of the gene expression. The value on the top represents the correlation p value, correlation coefficient and correlation calculation method.
