Cuproptosis-related gene *FDX1* expression correlates with the prognosis and tumor immune microenvironment in clear cell renal cell carcinoma

Tao Wang*, Yufeng Liu, Qing Li, Yang Luo, Dawei Liu and Bin Li

Department of Urology, The Fifth Affiliated Hospital of Southern Medical University, Guangzhou, China

Background: Cuproptosis, a newly discovered form of cell death, is regulated by protein lipoylation and is related to mitochondrial metabolism. However, further research is needed to determine how the cuproptosis-related gene ferredoxin 1 (*FDX1*) affects the tumor immune response and its prognostic significance in clear cell renal cell carcinoma (ccRCC).

Methods: The Cancer Genome Atlas was used to screen for *FDX1* gene expression in ccRCC and healthy tissue samples. The results were validated using the Gene Expression Omnibus and the Human Protein Atlas. Multivariable analysis and Kaplan-Meier survival curves were used to examine the relationship between *FDX1* gene expression, clinicopathological parameters, and overall survival (OS). The protein network containing *FDX1* gene interaction was constructed using the online Search Tool for the Retrieval of Interacting Genes/Proteins. The relationship between *FDX1* gene expression and immune cell infiltration in ccRCC was examined using Gene Ontology, gene set enrichment analysis (GSEA), and a single-sample GSEA. Using the Gene Expression Profiling Interactive Analysis and Tumor Immune Estimation Resource databases, we investigated the relationship between *FDX1* gene expression, the degree of immune cell infiltration, and the corresponding gene marker sets.

Results: ccRCC samples had significantly ($p < 0.05$) lower *FDX1* gene expression levels than normal tissue samples. Lower *FDX1* gene expression levels were strongly associated with higher cancer grades and more advanced tumor–node–metastasis stages. The findings of multivariate and univariate analyses illustrated that the OS in ccRCC patients with low *FDX1* expression is shorter than in patients with high *FDX1* expression ($p < 0.05$). Ferredoxin reductase and CYP11A1 are key proteins interacting with the *FDX1* gene, and ccRCC with an *FDX1* enzyme defect was associated with a low number of invading immune cells and their corresponding marker.

Conclusion: In ccRCC, decreased FDX1 expression was linked to disease progression, an unfavorable prognosis, and dysregulated immune cell infiltration.

KEYWORDS

ferredoxin 1, FDX1, clear cell renal cell carcinoma, immune cells, prognosis

Introduction

The number of people diagnosed with renal cell carcinoma (RCC) has increased steadily over the last several decades around the world. RCC has the highest annual mortality rate among urological tumors (1). RCC is heterogeneous cancer, with clear cell renal cell carcinoma (ccRCC) accounting for about 75–80% of cases (2). The initial disappearance of the von Hippel-Lindau tumor-suppressor gene expression in most ccRCC tumors distinguishes them from other cancers (3, 4). Targeted therapy is currently the standard treatment for ccRCC; nearly all patients eventually deteriorate as ccRCC cells escape drug-induced apoptosis or autophagy (5). Ferroptosis is a unique type of cell death, and its induction is gaining popularity as a viable therapeutic option for ccRCC (6–9). Identifying more promising therapeutic targets for ccRCC is crucial because current treatments only effectively treat a subset of patients. Furthermore, discovering additional biological markers that might aid in early diagnosis and improve prognosis is a critical endeavor.

Copper binds directly to the lipoylated components of the tricarboxylic acid (TCA) cycle, causing toxic protein stress and, cell death. This unique cell death mechanism is known as cuproptosis. Ferredoxin reductase (FDR), a mitochondrial flavoprotein, initiates the transfer of electrons from nicotinamide adenine dinucleotide phosphate (NADPH) to multiple cytochromes P450 using ferredoxin 1 (FDX1) and ferredoxin 2 as electron carriers. FDR, the only ferredoxin reductase in humans, is required to synthesize heme and iron-sulfur clusters and for steroidogenesis. The gene *FDX1* encodes a small iron-sulfur protein involved in synthesizing several steroid hormones and reducing mitochondrial cytochrome (10, 11). Furthermore, the *FDX1* gene can increase the copper-dependent cell death caused by elesclomol, which may offer a novel approach to improving the efficacy of many cancer-targeting drugs (12). Zhang Z found that knocking out the *FDX1* gene in lung adenocarcinoma did not result in apoptosis, aberrant cell cycle distribution, or inhibition of tumor cell proliferation. However, the *FDX1* gene may promote ATP production. Furthermore, the *FDX1* gene is strongly linked to glucose, fatty acids, and amino acid

metabolism (13). According to Zhen Zhang, HCC patients with high-FDX1 expression have a significantly longer survival time than HCC patients with low-FDX1 expression (14). However, the role of the *FDX1* gene in ccRCC remains unknown.

In this study, we used data from the Gene Expression Omnibus (GEO), the Cancer Genome Atlas (TCGA), and the Human Protein Atlas (HPA) databases to investigate the association between the *FDX1* gene expression, clinical data, and overall survival (OS) of ccRCC patients. Following that, we collected data from the Tumor Immune Estimation Resource (TIMER) and the Gene Expression Profiling Interactive Analysis (GEPIA) databases to examine the link between *FDX1* gene expression and immune cell infiltration and the associated gene marker sets. Furthermore, the FDX1-interacting protein network was analyzed using the online Search Tool for the Retrieval of Interacting Genes/Proteins (STRING) platform. A low *FDX1* gene level was related to reduced infiltrating immune cells in ccRCC tissues, indicating a dismal prognosis. Thus, it is plausible that the *FDX1* gene defect possibly debilitates antitumor immune effects in ccRCC. FDX1-related targeting may be a viable treatment approach in ccRCC along with/in combination with immunotherapy.

Materials and methods

Data source

TCGA (<https://portal.gdc.cancer.gov>), a publicly available data platform for a large-scale cancer genome project, provides clinicopathological data on 33 different types of cancer and is easily accessible to researchers and academics. The TCGA database was searched for clinical data on patients with ccRCC and high-throughput RNA sequencing (RNA-seq) information. The fragments per kilobase per million fragments mapped (FPKM) approach included in HTSeq was used to determine transcript expression levels. Furthermore, for the subsequent investigation, the RNA-Seq gene expression level 3 HTSeq-FPKM data of 539 patients with ccRCC and the clinical data were transformed into the format of transcripts per million (TPM) reads. Because the database is public, no permission from the local ethics committee was necessary.

The GEO and HPA databases

The GEO database, which includes one of the world's largest collections of gene chips, is a complete and comprehensive gene expression resource at the National Center for Biotechnology Information (<https://www.ncbi.nlm.nih.gov/geo/>). The HPA contains extensive data on the transcriptome and proteome of various human specimens, including tissue, cell, and pathology atlases. Currently, this web-based database contains data on the cell-specific positions of 44 normal tissues and twenty of the most frequently diagnosed cancers. Moreover, the database also provides data on protein immunohistochemistry in tumors and normal human tissue samples.

Clinical statistical analysis of prognosis, model development, and assessment

Prognostic parameters, such as OS, disease-specific survival (DSS), and progression-free interval (PFS) were analyzed using patient data from the TCGA in the clinical meaning module of the Xiantao platform (<https://www.xiantao.love/>). These analyses were performed using the Cox regression and Kaplan–Meier methods. The median value was used to determine the threshold value of the low and high *FDX1* gene expression groups. We used the Wilcoxon signed-rank sum test in conjunction with logistic regression to determine the relationship between clinical-pathological characteristics and *FDX1* gene expression. A multivariate Cox regression model was used to investigate the effect of *FDX1* gene expression on the likelihood of survival and other clinical variables. A p-value of less than 0.05 was set as the threshold for significance. The Cox regression model findings were combined with the independent prognostic variables obtained from the multivariate analysis, and the survival probabilities for 1, 3, and 5 years were projected using these data. The projected odds were compared to actual occurrences using calibration curves. The 45-degree line represented the most accurately predicted value.

Comprehensive protein-protein interaction analysis

The STRING web platform (<https://string-db.org/>) was also adapted for data analysis. This website provides extensively integrated and consolidated PPI data. After importing the *FDX1* expression data into the STRING platform, we retrieved information from the PPI network. The significance threshold was set at a confidence score greater than 0.7.

Enrichment analysis

The gene ontology (GO) enrichment analysis of the *FDX1* gene expression was performed using R's clusterProfiler program

(version 3.6.3) and included analyses of molecules with differential expression, particularly those classified as cellular components (CC), molecular functions (MF), and biological processes (BP). The following parameters were changed: enrichment factor > 1.5, minimum count > 3, and $p < 0.01$. For each study, the gene set enrichment analysis (GSEA) (15) method was used to rank the genome a thousand times and enrich pathways associated with *FDX1* gene expression. In the GSEA analysis, the threshold value for statistically significant findings was determined to be an adjusted $p < 0.05$ and a false discovery rate (FDR) of < 0.25 . The enrichment analysis results were defined using the normalized enrichment scores (NESs) and adjusted p-values. The Cluster Profiler tool was used for the GSEA and the visualization (16).

Analysis of the infiltration of immune cells

Bindea G et al. (17) published a research report that was used to obtain the marker genes for each of the 24 different types of immune cells. The ssGSEA method investigated tumor infiltration using 24 different types of immune cells. The Spearman correlation algorithm was used not only to compare immune cell infiltration levels between subgroups with high and low *FDX1* gene expression but also to evaluate the strength of association between *FDX1* gene expression and infiltrating concentrations of the 24 distinct types of immune cells. The link between *FDX1* gene expression and immune infiltration, as well as the association between infiltrating levels of immune cells and the values obtained in various *FDX1* gene expression subgroups, were analyzed in the module of the “Xiantao tool” based on the findings of immune infiltration, Xiantao tool Spearman correlation, and Wilcoxon signed-rank sum. A p-value < 0.05 was considered statistically significant (* $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$; and **** $p < 0.0001$).

Gene correlation analysis

GEPIA (<http://gepia.cancer-pku.cn/index.html>) is a web platform that provides information on 9,736 cancer types and 8,587 normal specimens derived from TCGA and GTEx. It usually focuses on the analysis of the RNA-seq findings. The Gene and Isoform classes each specify the types of the corresponding number of types of genes and isoforms, which total 60,498 and 198,619, respectively. An investigation was conducted in the GEPIA database to determine the relationship between the expression of the *FDX1* gene and various immune cell markers. The degree of expression of the *FDX1* gene is shown along the x-axis, whereas the expression of other relevant genes is shown on the y-axis. Furthermore, using data from TIMER (<http://cistrome.org/TIMER/>), we confirmed

the expression of genes with a strong relationship to *FDX1* gene expression in GEPIA. A p-value < 0.05 was considered statistically significant (*p < 0.05; **p < 0.01; ***p < 0.001; and ****p < 0.0001).

Results

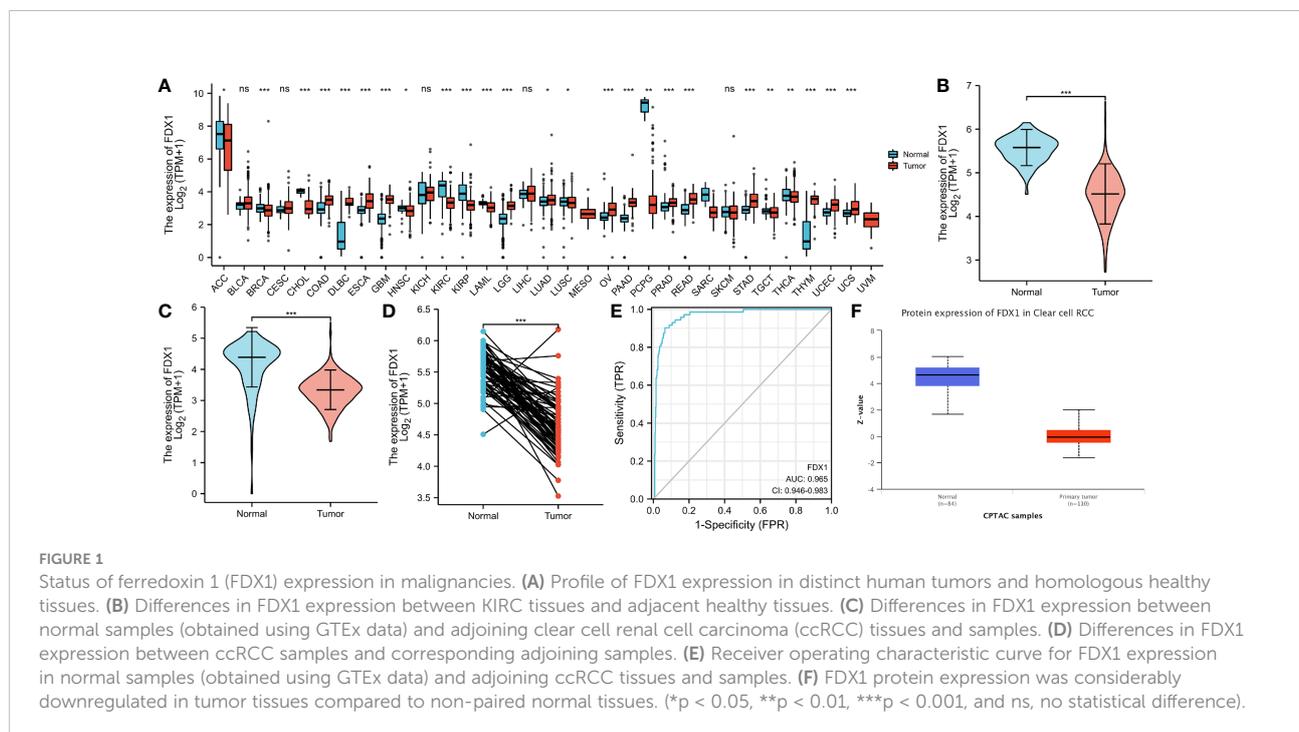

FDX1 gene expression was decreased in tumors as opposed to normal samples

To determine whether low *FDX1* gene expression in cancer is a generalized phenomenon, we analyzed the *FDX1* gene expression in pan-cancer samples and compared it to that in adjacent healthy tissue samples in the TCGA dataset (Figure 1A). The TCGA database was used to make predictions about the patterns of *FDX1* messenger RNA (mRNA) expression in 539 ccRCC and 72 normal tissue specimens (Figure 1B). In ccRCC primary tumor specimens, *FDX1* mRNA expression was significantly (p < 0.001) lower than in normal tissue specimens. Furthermore, we compared *FDX1* expression in normal tissue specimens (data obtained from GTEx) to that of adjoining ccRCC tissues and that of ccRCC tissue specimens and discovered that *FDX1* expression was downmodulated in ccRCC specimens (p < 0.001) (Figure 1C). Moreover, *FDX1* expression was substantially downmodulated in 72 ccRCC samples compared to corresponding adjoining samples (p < 0.001) (Figure 1D). Subsequently, a receiver operating characteristic (ROC) curve was constructed to

examine the diagnostic significance of *FDX1* expression by comparing *FDX1* expression in normal tissue specimens (data obtained from GTEx) and adjoining ccRCC tissues with that of ccRCC specimens. The findings illustrated that the area under the curve (AUC) value for *FDX1* levels was 0.965 (confidence interval = 0.946–0.983), indicating a strong potential for diagnostic use (Figure 1E). The level of *FDX1* protein expression was also reduced in ccRCC tissues when compared to normal tissue specimens (Figure 1F). This indicates that *FDX1* protein and mRNA expression patterns were comparable across databases. Furthermore, the level of the *FDX1* gene expression in the GEO datasets (GSE66271 and GSE53757) was checked for accuracy (Figures 2A, B). Similarly, using HPA data, the expression of the *FDX1* protein was shown to be downmodulated in ccRCC tissue compared to normal tissue (Figure 2C).

Association of *FDX1* expression with clinical parameters

The proportion of *FDX1* expression in tumor specimens was determined using the Z-score criterion, and the ccRCC cohort was then classified into low- and high-expression groups based on *FDX1* expression levels. The Kruskal-Wallis and Wilcoxon signed-rank tests were used to determine the relationship between *FDX1* expression and clinical parameters. Higher T stage, N stage, M stage, and pathological stages, as well as primary therapy outcomes (PD) and OS events (dead) (p <

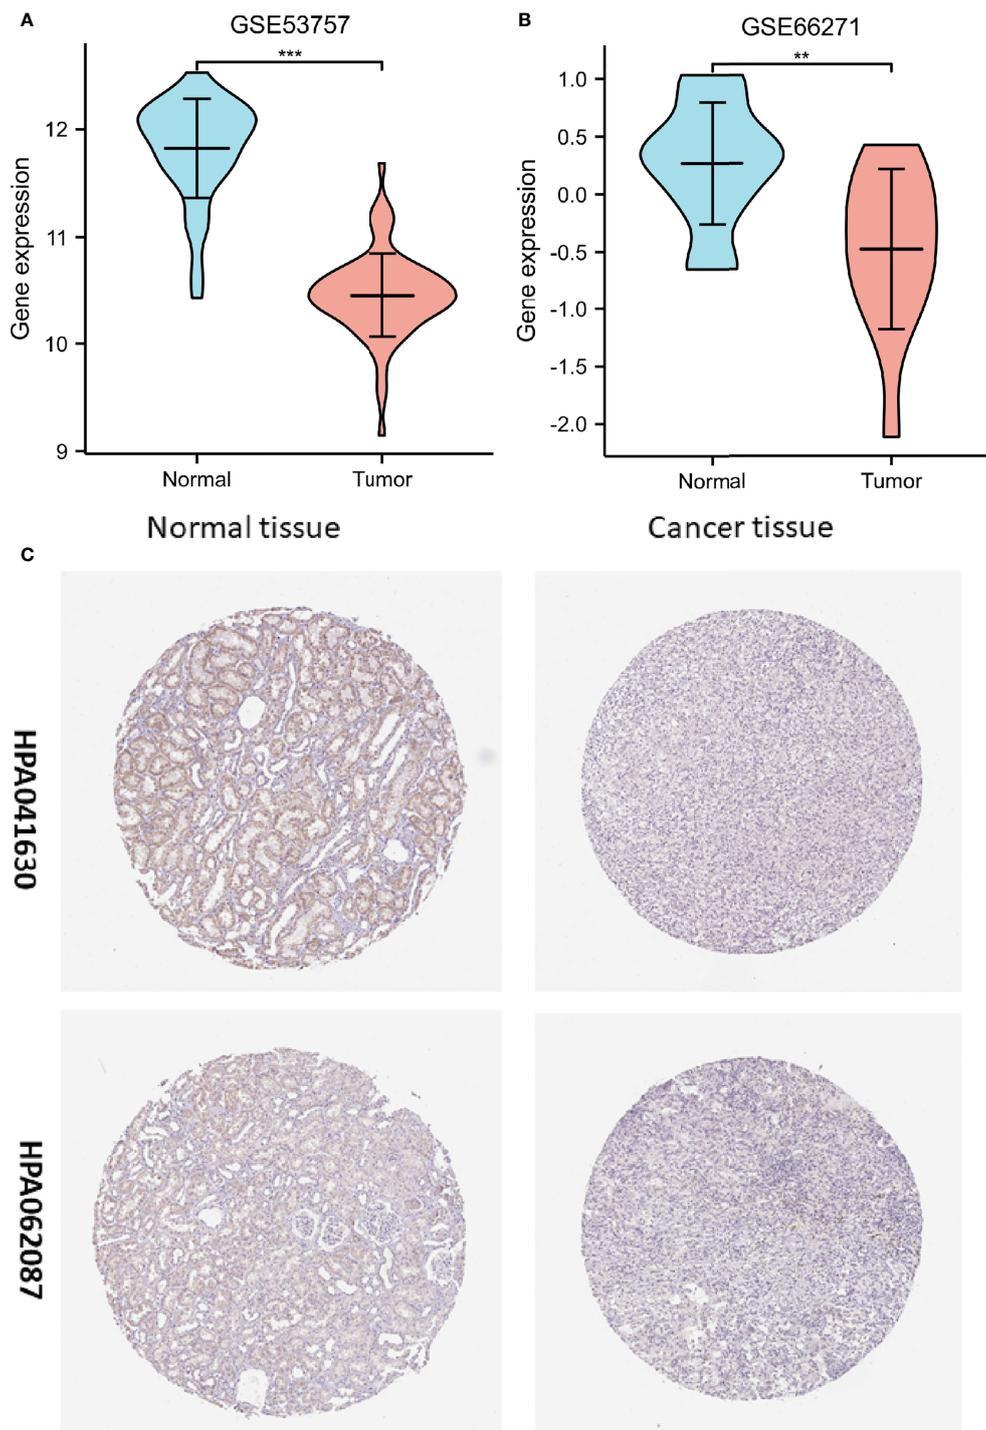

FIGURE 2

Assessment of the ferredoxin 1 (*FDX1*) gene expression data from the Gene Expression Omnibus datasets and the Human Protein Atlas (HPA). **(A)** Verification of the decreased *FDX1* messenger RNA (mRNA) expression in clear cell renal cell carcinoma (ccRCC) compared to normal tissues in the GSE53757 dataset. **(B)** Verification of the decreased *FDX1* mRNA expression in ccRCC compared to normal samples in the GSE66271 dataset. **(C)** In the HPA data, *FDX1* protein expression in renal cell carcinoma tissue was lower than in normal tissue in the HPA data (Antibody HPA041630, HPA062087, and 10X). (** $p < 0.01$, and *** $p < 0.001$).

0.05, Figures 3A–F), were associated with lower FDX1 expression. Concurrently, similar findings were obtained after conducting the Fisher's exact test or the chi-square test (Table 1). Furthermore, the findings of the univariate analysis of FDX1 expression revealed a strong association between FDX1 expression and clinical parameters, particularly pathological grade (odds ratio (OR) = 0.573 (0.402–0.814), $p = 0.002$), histological grade (OR = 0.639 (0.453–0.900), $p = 0.011$), and T stage (OR = 0.609 (0.425–0.868), $p = 0.006$) (Table 2). However, no statistically significant difference in the association with the N stage (OR = 0.429 (0.132–1.217), $p = 0.127$), or age (OR = 0.964 (0.687–1.351), $p = 0.829$) was found (Table 2). Based on these findings, FDX1 expression was linked to the clinical features of ccRCC.

Prognostic relevance of FDX1 expression in ccRCC

Figures show the relationships between FDX1 expression and prognosis indicators based on data from the TCGA database (OS, DSS, and PFS). Low FDX1 expression was associated with unfavorable OS (hazard ratio (HR) = 0.51(0.37–0.69), $p < 0.001$, Figure 4A), DSS (HR = 0.40 (0.27–0.60), $p < 0.001$, Figure 4B),

and PFS (HR = 0.57 (0.41–0.79), $p < 0.001$, Figure 4C). Individuals with ccRCC had elevated risk scores and low levels of FDX1 expression, whereas those with low-risk scores had significant levels of FDX1 expression. Furthermore, the association between FDX1 expression and the various groups was investigated in this study. FDX1 expression was found to be low in the T3–T4 stage (HR = 0.58 (0.39–0.86), $p = 0.007$), pathological-grade III–IV [HR = 0.63 (0.44–0.91), $p = 0.015$], and histological-grade G3–G4 (HR = 0.60 (0.42–0.85), $p = 0.005$) (Figure 4D). A clinical prognostic risk score for ccRCC was created using M stage, pathological grade, N stage, histological grade, age, T stage, and FDX1 expression (Figure 4E). We also used a calibration chart to assess how accurate the model's predictions were (Figure 4F). The FDX1 expression might provide a more accurate prediction of patients' survival probabilities over 3 and 5 years. Overall, FDX1 expression was shown to correlate with the prognosis of patients with ccRCC.

Constructing PPI networks

It is critical to understand the functional interactions that occur between proteins to understand the molecular basis and metabolic processes involved in cancer. An analysis of the PPI network of

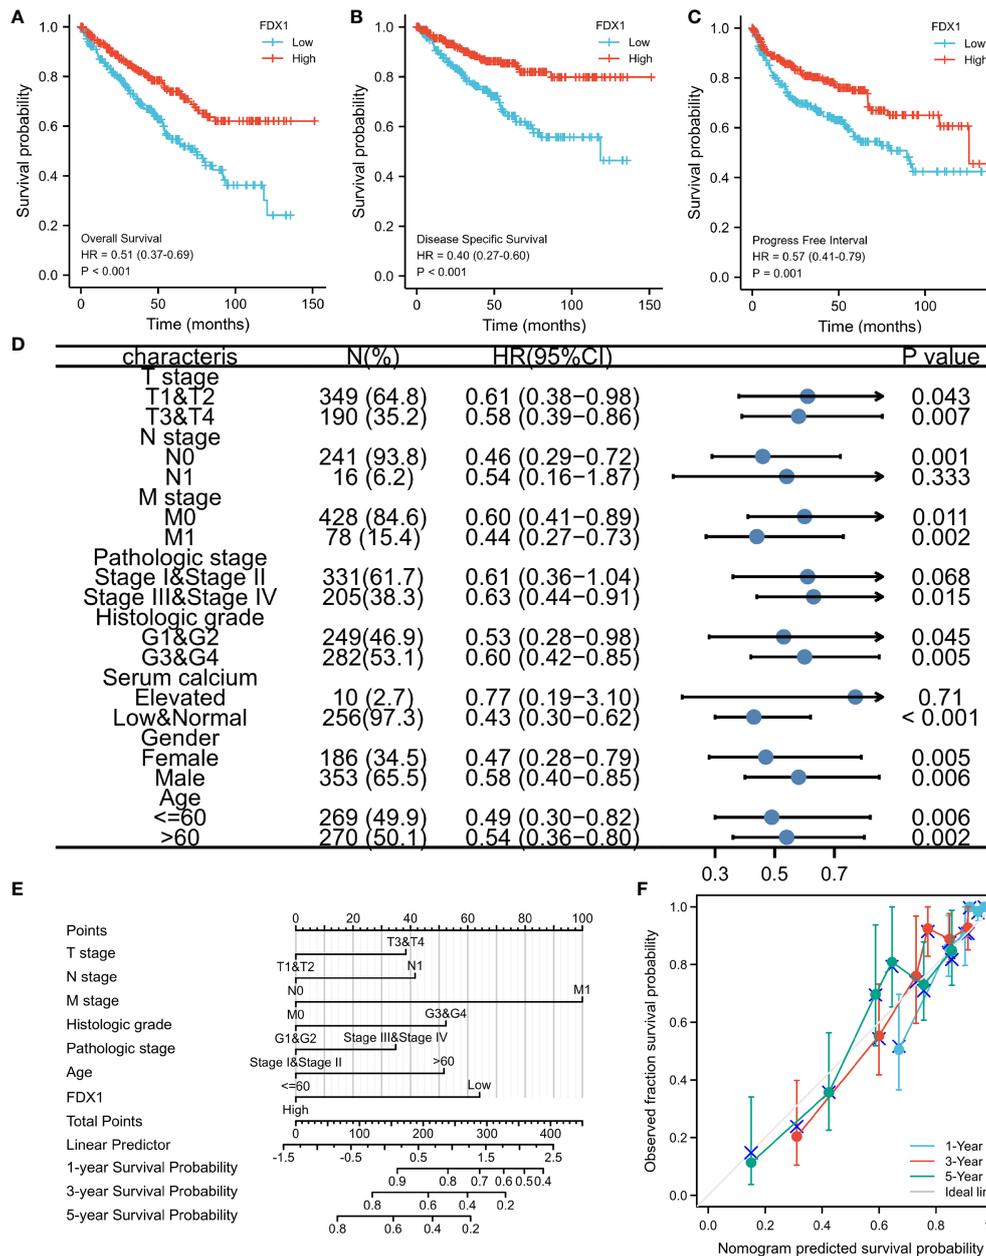

FIGURE 4 Ferredoxin 1 (FDX1) expression prognostic analysis. Patients with low FDX1 expression had unfavorable prognosis indicators than patients with high FDX1 expression, including shorter overall survival (OS) (A), progression-free interval (PFI) (B), and disease-specific survival (DSS) (C) (both log-rank p < 0.001). (D) Prognosis based on FDX1 expression in distinct kinds of clinical features (OS). (E) A multivariate analysis nomogram based on clinical features associated with FDX1 expression. (F) The calibration chart displays the model's prediction accuracy as determined using multi-factor Cox regression analysis.

FDX1 was performed using the STRING program to determine the protein interactions involved in the development of ccRCC. Figure 5 shows the topmost ten proteins along with their associated gene names, scores, and annotations, including *FDXR*, *CYP11A1*, *ISCU*, *NFS1*, *CYCS*, *AKR1B1*, *FXN*, *LYRM4*, *HSCB*, and *STAR*.

Expression of the FDX1 gene to the expression pattern of whole genes

An analysis of the *FDX1* gene expression profile was performed to gain a better understanding of the biological

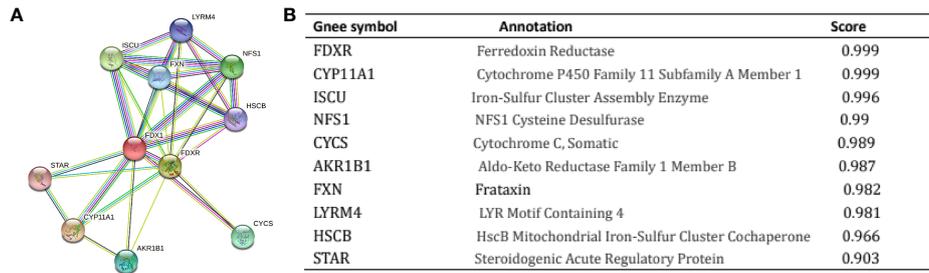

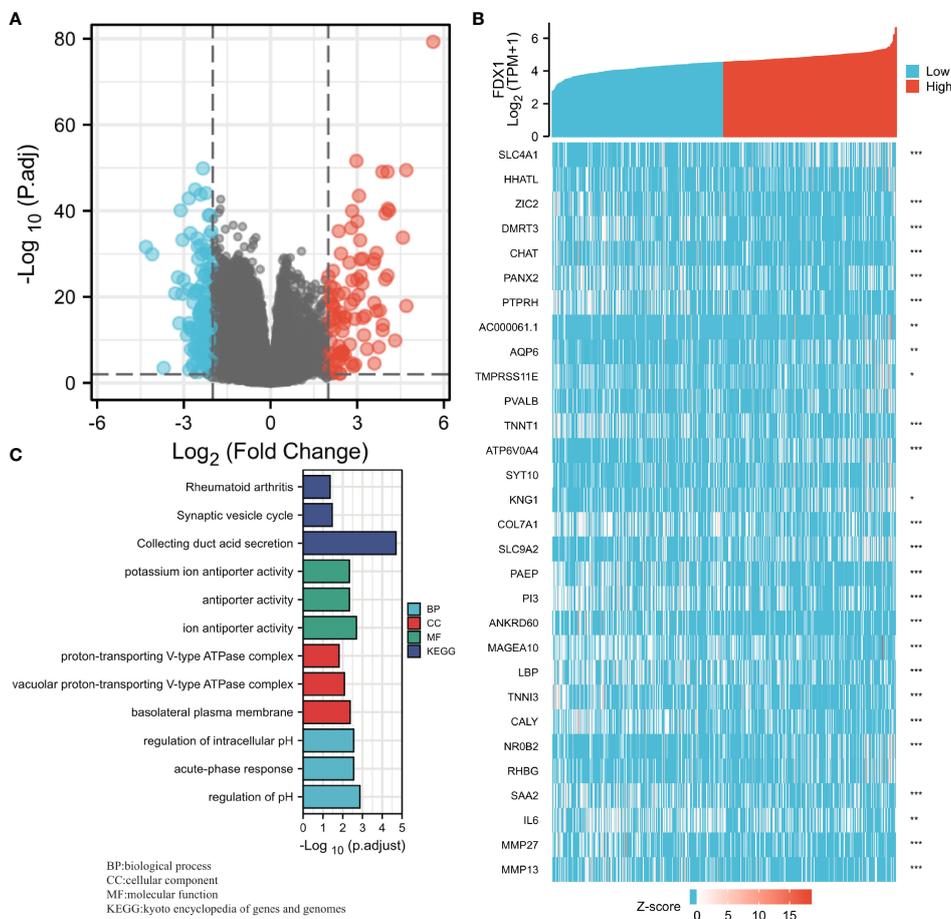

FIGURE 5 Proteins interacting with Ferredoxin 1 (FDX1) in clear cell renal cell carcinoma tissue. Annotation of proteins that interact with FDX1 (A), along with their respective co-expression scores (B).

role of the *FDX1* gene in ccRCC. It was discovered that the expression of 3,805 genes that were in a downmodulated and 171 genes that were in an upmodulated were substantially linked to the *FDX1* gene

expression ($\log_{2}FC > 1$ and $p_{adj} < 0.05$) (Figure 6A). Additionally, the top 30 genes with aberrant expression levels ($abslog_{2}FC > 2$ and $p_{adj} < 0.01$) were displayed on the gene expression heat map (Figure 6B). Moreover, GO

enrichment analysis was performed based on the *FDX1* gene expression results. The BP primarily associated with the *FDX1* gene was the regulation of pH, acute-phase response, intracellular pH regulation, cellular pH regulation, and monovalent inorganic cation homeostasis, among others (Table 3, Figure 6C).

GSEA of the *FDX1* gene expression

Using TCGA gene expression data, GSEA was performed to determine biological and functional pathways between high- and low-*FDX1* gene expression groups. Based on the NESs, the enrichment signaling pathway that was determined to be the most relevant for *FDX1* gene expression was chosen (Figure 7). The GSEA analysis illustrated that the low *FDX1* gene expression phenotype was predominantly concentrated in reactome_cd22_mediated_bcr_regulation (A), reactome_fcgr_activation (B), reactome_creation_of_c4_and_c2_activators (C), reactome_scavenging_of_heme_from_plasma (D), reactome_role_of_lat2_ntal_lab_on_calcium_mobilization (E), and reactome_antigen_activates_b_cell_receptor_bcr_leading_to_generation_of_second_messengers (F).

Relationship between the *FDX1* gene expression and immune cell infiltration

The relationship between the *FDX1* gene expression and 24 distinct immune cell subtypes in ccRCC was investigated and analyzed. The *FDX1* gene expression had a strong positive correlation with neutrophils, Tgd cells, and mast cell infiltration and a strong inverse correlation with Treg, aDC, and cytotoxic cell infiltration, among other things (Figures 8A, E–J). Further investigation illustrated substantial variations in the *FDX1* gene expression level in different infiltrating immune cells, notably aDC, pDC, mast cells, TReg, neutrophils, cytotoxic cells, and NK CD56bright cells, among other things (Figures 8B–D). To effectively examine the possible function of the *FDX1* gene in influencing the infiltration status of distinct immune cells in ccRCC, we used data from the TIMER and GEPIA databases to establish the link between the *FDX1* gene and different immune marker sets, which are commonly known as indicators of various immunocytes, including DCs, NK cells, M1/M2 macrophages, neutrophils, tumor-associated macrophages (TAMs), B cells, monocytes, T cells (general), and CD8+ T cells, in ccRCC (Table S1). Furthermore, this study evaluated different functional T cell subtypes, such as Tregs, exhausted T cells, Th1, Th2, Th9, Th17, Th22, and Tfh. According to the findings, the expression of most immune set markers for various types of DCs, M1/M2

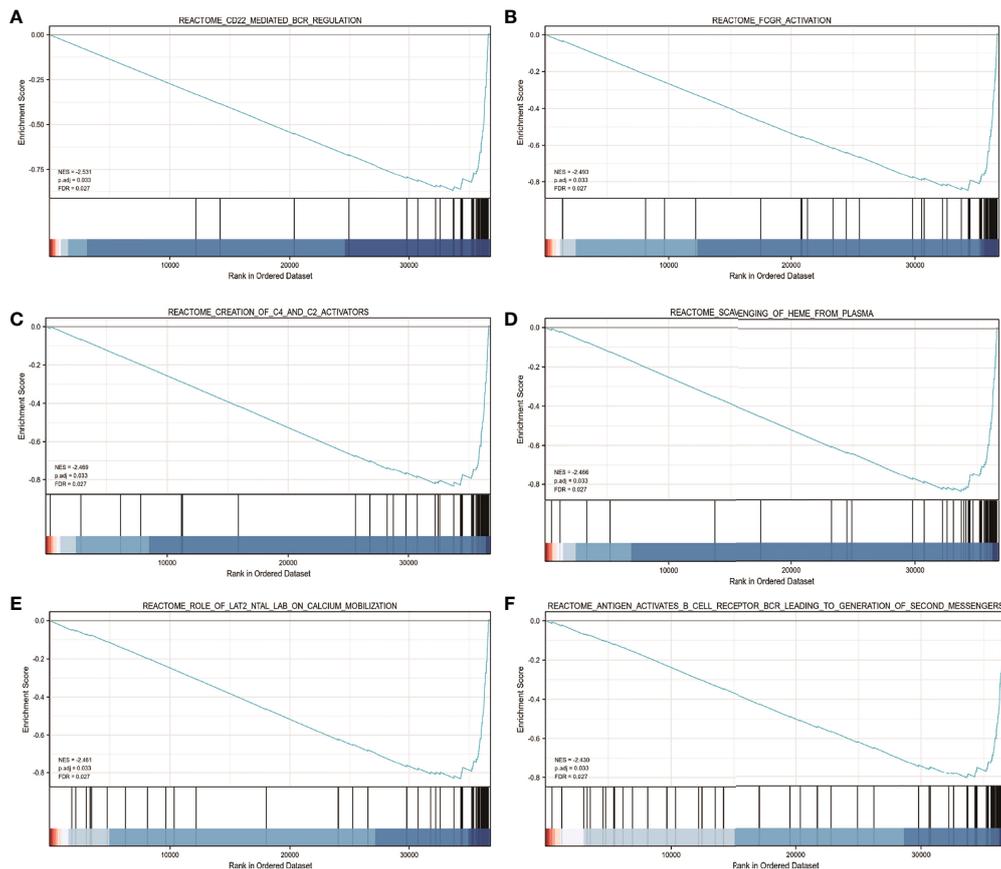

FIGURE 7

The findings of the gene set enrichment analysis (GSEA). GSEA results showed that reactome_cd22_mediated_bcr_regulation (A), reactome_fcgr_activation (B), reactome_creation_of_c4_and_c2_activators (C), reactome_scaevenging_of_heme_from_plasma (D), reactome_role_of_lat2_ntal_lab_on_calcium_mobilization (E), and reactome_antigen_activates_b_cell_receptor_bcr_leading_to_generation_of_second_messengers (F) were enriched primarily in *FDX1*-associated ccRCC. ES, Enrichment score; FDR, false discovery rate; NES, normalized ES.

macrophages, TAMs, and T cells was shown to be linked to the level of *FDX1* gene expression in ccRCC.

Discussion

The leading causes of death have changed over time. According to previous research, ccRCC is one of the most prevalent tumors and a major cause of male cancer-related mortality. As a result, researchers have conducted numerous studies on ccRCC to understand it better. In this study, we found a strong correlation between the *FDX1* gene and the OS of ccRCC patients. The prognostic model was built using the Cox regression model. Patients with ccRCC were divided into low- and high-risk groups, with the low-risk group having a poor prognosis. Furthermore, the univariate and multivariate Cox analyses revealed that the *FDX1* gene was an independent prognostic factor in ccRCC.

Because the *FDX1* gene encodes a reductase that reduces Cu^{2+} to a more toxic Cu^{1+} , given the pivotal role of the *FDX1* gene in cuproptosis, we hypothesized that the *FDX1* gene might help to evaluate the occurrence of this copper-induced cell death in ccRCC. *FDX1* gene expression was significantly lower in ccRCC samples than in normal kidney tissues (Figures 1B–D), indicating resistance to cuproptosis. In addition, ccRCC patients with a lower *FDX1* gene expression have a shorter survival time (Figures 4A–C), probably due to the survival advantage of these tumor cells by resisting copper-induced toxicity.

Tumor onset and progression are strongly linked to the immune microenvironment and abnormal metabolism. Moreover, evidence indicates that metabolism is crucial to the onset and progression of cancer (18, 19). For instance, glucose and lactic acid metabolism changes have been linked to lung cancer (20, 21). A recent study demonstrated that E2F1 promotes the growth and metastasis of ccRCC cells by activating the SREBP1-dependent fatty acid production

MRC1, had a moderate correlation with the *FDX1* gene expression, illustrating a potential regulatory function of the *FDX1* gene expression in TAM polarization. Similarly, Zhen Zhang reported that the *FDX1* expression level is positively associated with the abundance of B cells ($p = 2.33 \times 10^{-3}$) and macrophages ($p = 1.73 \times 10^{-2}$) (30). We also discovered that the expression of CD4+ T cell markers, including CD4, correlates positively with *FDX1* expression. CD4+ T cells are extremely versatile, performing various critical functions in developing and maintaining effective antitumor immunity and protumor functions (31). CD4+ T cells play a role in tumor invasion and progression (32) in the tumor microenvironment. In advanced kidney renal clear cell carcinoma (KIRC), immunotherapy has recently evolved from traditional immunoboosts of interferon α and interleukin-2, causing frequent immune-related adverse events to the more effective and less toxic immune normalization with programmed cell death 1 (PD-1) or cytotoxic T lymphocyte-associated antigen 4 (CTLA4) antibodies (33). Our study found that T cell exhaustion markers such as PD-1, CTLA4, and LAG3 negatively correlate with *FDX1* expression. Previous studies have shown that patients with high PD-1 expression can benefit from anti-PD-1 therapy (34). These findings suggest that *FDX1* may be critical in the onset and progression of ccRCC and immunoregulatory processes and may also affect immune cell infiltration and the outcome of immunotherapy. Therefore, targeting *FDX1* may become an alternative strategy for tumor therapy.

However, this study has some limitations. First, the current study was based on data retrieved from an online database, and further studies with clinical samples are needed to confirm our study findings. Second, we primarily focused on the bioinformatics analysis of *FDX1* expression data without experimental validation, and it is necessary to study the mechanism underlying *FDX1* expression *in vitro* and *in vivo*. Finally, further research on the biological impact of *FDX1* on ccRCC cells is necessary.

Conclusions

In conclusion, *FDX1* is downregulated in advanced ccRCC, which may affect the ccRCC progression *via* key molecular functions and pathways. Furthermore, attenuated *FDX1* expression was responsible for a poor prognosis. Furthermore, *FDX1* expression was linked to the infiltration levels of distinct immune cells, notably neutrophils, Tgd, mast cells, Treg, aDC, and cytotoxic cells. In the future, both *in vitro* and *in vivo* research will be warranted to bioinformatics analysis findings and explain the possible function of *FDX1* in ccRCC.

Data availability statement

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found in the article/Supplementary Material.

Author contributions

TW: Project development, data collection, and manuscript writing. YFL: Data collection and manuscript editing. YL and QL: Data collection, and manuscript editing. DW L and BL: Data analysis and supervision. All authors have read and approved the manuscript.

Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.
