Ginkgo biloba is the most popular phytotherapeutic agent used worldwide for treatment of several human disorders. However, the mechanisms involved in the protective actions of *Ginkgo biloba* on cardiovascular diseases remain poorly elucidated. Taking into account recent studies showing beneficial actions of cholinergic signaling in the heart and the cholinergic hypothesis of *Ginkgo biloba*-mediated neuroprotection, we aimed to investigate whether *Ginkgo biloba* extract (GBE) promotes cardioprotection via activation of cholinergic signaling in a model of isoproterenol-induced cardiac hypertrophy. Here, we show that GBE treatment (100 mg/kg/day for 8 days, v.o.) reestablished the autonomic imbalance and baroreflex dysfunction caused by chronic β -adrenergic receptor stimulation (β -AR, 4.5 mg/kg/day for 8 days, i.p.). Moreover, GBE prevented the upregulation of muscarinic receptors (M_2) and downregulation of β_1 -AR in isoproterenol treated-hearts. Additionally, we demonstrated that GBE prevents the impaired endothelial nitric oxide synthase activity in the heart. GBE also prevented the pathological cardiac remodeling, electrocardiographic changes and impaired left ventricular contractility that are typical of cardiac hypertrophy. To further investigate the mechanisms involved in GBE cardioprotection *in vivo*, we performed *in vitro* studies. By using neonatal cardiomyocyte culture we demonstrated that the antihypertrophic action of GBE was fully abolished by muscarinic receptor antagonist or NOS inhibition. Altogether, our data support the notion that antihypertrophic effect of GBE occurs via activation of M_2 /NO pathway uncovering a new mechanism involved in the cardioprotective action of *Ginkgo biloba*.

Keywords: *Ginkgo biloba*, cardiac hypertrophy, chronic β -adrenergic stimulation, cholinergic signaling, endothelial nitric oxide synthase

INTRODUCTION

Ginkgo biloba extract (GBE) has been recognized in the traditional Chinese medicine for its various therapeutic actions. GBE is composed of several components such as bilobalide, ginkgolide A, ginkgolide B, and ginkgolide C, which are responsible for its multiple pharmacological effects (Yoshikawa et al., 1999). However, although *G. biloba* leaves are widely prescribed as alternative herbal medicine for memory improvement, as well as for dementia (Tan et al., 2015), the precise mechanism by which *G. biloba* elicits neuroprotective and cognitive-enhancing effects remains to be determined. Notably, the cholinergic hypothesis, associated with augmented yield of the neurotransmitter acetylcholine (ACh), has been consistently reported as the primary mechanism of the beneficial pharmacological properties of *G. biloba* (Nathan, 2000; Kehr et al., 2012).

Although the benefits of GBE on neurological disorders are well known (Nathan, 2000; Tan et al., 2015), GBE has also been used for treatment of several cardiovascular diseases (Zhou et al., 2004; Kuller et al., 2010). However, most of the studies have attributed the cardioprotection of GBE to enhanced antioxidant activity (Pietri et al., 1997; Liebgott et al., 2000; Wang et al., 2016). Accordingly, augmented endogenous antioxidant enzymes mediated by GBE treatment led to a protective effect against acute myocardial infarction and injury caused by ischemia-reperfusion (Trumbeckaite et al., 2007; Panda and Naik, 2008). Moreover, the anti-inflammatory and antiapoptotic actions of GBE have been also involved in the attenuation of doxorubicin-induced cardiac injury (Liu et al., 2008). Altogether, these studies support the notion that GBE might be a promising cardiac agent against various pathological stimuli.

Despite the extensive body of evidence supporting the beneficial cardiac actions of GBE, the mechanisms involved are still unclear. Nitric oxide (NO) signaling has been consistently reported as a unique modulator of cardiovascular system under physiological and pathophysiological conditions (Barouch et al., 2002; Umar and van der Laarse, 2009). Accordingly, endothelial nitric oxide synthase (eNOS)-overexpressing mice display attenuated isoproterenol-induced cardiac hypertrophy (Ozaki et al., 2002), while eNOS knockout mice show a higher incidence of early afterdepolarization events associated with contractile dysfunction (Barouch et al., 2002; Wang et al., 2008). Moreover, impaired eNOS activity has been found in many forms of diseases such as hypertension (Chou et al., 1998), cardiac hypertrophy (Ozaki et al., 2002; Champion et al., 2004), myocardial infarction and ischemia-reperfusion injury (du Toit et al., 2007; Nakata et al., 2008), and heart failure (Couto et al., 2015). Notably, GBE has been also shown to enhance eNOS activity and, consequently, NO bioavailability in human endothelial cells (Koltermann et al., 2007). In line with these findings, GBE causes vasodilation on different vascular beds (Satoh and Nishida, 2004), being also involved in the restoration of impaired endothelial-dependent vasodilation in hypertensive rats (Kubota et al., 2006; Koltermann et al., 2007). Recently, the cardioprotective actions of GBE against adriamycin-induced acute cardiotoxicity have been reported

by regulation of inflammatory and NO signaling pathways (El-Boghdady, 2013).

Thus, in spite of many clues indicating that GBE may be therapeutically relevant by balancing NO production, its involvement on the antihypertrophic effect of GBE is not yet reported. Therefore, based on the above considerations, the present study aimed to evaluate whether *G. biloba* promotes cardioprotection in a model of isoproterenol-induced cardiac hypertrophy and the mechanisms involved in these effects.

MATERIALS AND METHODS

Animals

Male Wistar rats (250–270 g) were obtained from the Animal Care Facility of Federal University of Sergipe and maintained under a controlled 12-h light/12-h dark cycle at room temperature ($23 \pm 2^\circ\text{C}$). All experimental procedures were previously approved by the Ethics Committee for Animal Research of the Federal University of Sergipe, Brazil (Protocol #36/10).

Experimental Groups

Animals were randomly divided into four experimental groups and the treatments were performed for 8 days: CTR, received saline (i.p. daily); ISO, received isoproterenol (4.5 mg/kg/day, i.p.); GBE, received *G. biloba* extract (100 mg/kg/day, v.o.) plus saline (i.p.); ISO + GBE, received isoproterenol (4.5 mg/kg/day, i.p.) plus *G. biloba* extract (100 mg/kg/day, v.o.). Isoproterenol was used as a non-specific β -adrenergic receptor (β -AR) agonist to induce cardiac hypertrophy, as previously described (Gavioli et al., 2014). The GBE used in this study was a standardized extract obtained from leaves, in which containing 25.5% Ginkgo flavonoids, 24.14% quercetin, 0.86% kaempferol, 0.55% isorhamnetin, and 6% terpenoids (ginkgolides and bilobalide). The GBE was provided by FÁrmacos (Sergipe) from Ningbo Traditional Chinese Pharmaceutical (China).

Hemodynamic Measurements

The animals were anesthetized with thiopental sodium (50 mg/kg, i.p.) and a polyethylene catheter was implanted into the femoral artery. The catheter was tunneled into the back of the rats and exteriorized in the nape. After 24 h, the catheter was connected to a pressure transducer (FE221, Bridge Amp, ADInstruments, Bella Vista, NSW, Australia) coupled to a pre-amplifier (Powerlab 8/35, ADInstruments). Blood pressure and heart rate (HR) were recorded for 30 min and processed using a dedicated software (LabChart 7 Pro, ADInstruments).

Autonomic Evaluation

Cardiac autonomic balance was evaluated by frequency domain (Macedo et al., 2016). To perform this analysis, the CardioSeries v2.4 software was used¹. First, the beat-by-beat series obtained from pulsate arterial pressure recordings and HR were converted to data points every 100 ms using cubic

¹<http://sites.google.com/site/cardiorieseries>

spline interpolation (10 Hz). The interpolated series were divided into half-overlapping sequential sets of 512 data points (51.2 s). Before calculation of the spectral power density, the segments were visually inspected and the non-stationary data were not taken into consideration. The spectrum was calculated using the Fast Fourier Transformation algorithm and Hanning window was used to attenuate side effects. The spectrum is composed by bands of low frequency (LF; 0.2–0.75 Hz) and high frequency (HF; 0.75–3 Hz), being the results expressed as normalized units (nu), by calculating the percentage of the LF and HF variability with respect to the total power after subtracting the power of the very LF component (VLF frequencies < 0.20 Hz), namely LF/HF ratio. HF indicates the cardiac parasympathetic activity, while LF is an index of cardiac sympathetic activity and LF/HF ratio represents the sympatho-vagal balance to the heart.

The baroreflex sensitivity (BRS) was measured in the time domain by the sequence method (Bertinieri et al., 1985). Sequences of at least four heart beats with increased SAP followed by pulse interval lengthening or subsequent decrease of SAP with pulse interval shortening with correlation greater than 0.85 were identified as baroreflex sequence. The slope of the linear regression between SAP and pulse interval was considered as a measure of BRS (mmHg/s).

Electrocardiography (ECG) Records

The rats were anesthetized and kept in the supine position with spontaneous breathing. For surface ECGs recording, three stainless steel electrodes were subcutaneously implanted and ECG signals were amplified (HP7754A, HP7754B, Hewlett-Packard, Chicago, IL, USA), digitalized (DI-710, Windaq Pro, Dataq, Akron, OH, USA) and stored in a computer for off-line processing. In all of the experimental groups, HR, corrected QT interval (QTc), QRS complex duration, and intrinsicoid deflection (ID) were measured in 10 consecutive beats. QT interval was corrected by HR using Bazett's equation.

Measurements of Left Ventricular Developed Pressure (LVDP) and Coronary Pressure

After 15 min of heparin administration (1,000 I.U., i.p.), the heart was quickly removed and carefully mounted in an aortic perfusion system (Langendorff technique) on a constant flow (8 mL/min) (Milan Peristaltic Pump, Paraná, Brazil). Then, the heart was perfused with Krebs solution (in mM: 118.0 NaCl, 4.7 KCl, 1.2 MgSO₄, 25.0 NaHCO₃, 1.8 CaCl₂, 11.1 glucose, 1.2 KH₂PO₄; pH was adjusted to 7.4) that had been previously filtered through a cellulose acetate membrane (0.45 μm), oxygenated (95% O₂ + 5% CO₂) and kept at 37 ± 0.1°C (Haake F3, Berlin, Germany). The left intraventricular pressure was measured using a water-filled balloon introduced into the cavity of the left ventricle. This device was coupled to a pressure transducer (HP 1290A, Hewlett-Packard, Chicago, IL, USA). Signals were amplified (HP7754A, HP7754B), digitized (DI-710, Windaq Pro, Dataq, Akron, OH, USA) and stored in a computer. The system was calibrated using a mercury column. Coronary

pressure was measured at the tip of the aortic cannula and monitored in a water column.

Western Blot Analyses

Western blots were performed as previously described (Mota et al., 2015), with some modifications. Thirty to fifty microgram of protein were resolved on SDS-PAGE, transferred to a PVDF membrane, and incubated with the following primary antibodies: anti-eNOS (1:1000, sc-654), anti-nNOS (1:1000, sc-8309), M₂ (1:1000, sc-9107) anti-peNOS^{ser1177} (1:1000, sc-12972), anti-pnNOS^{ser852} (1:1000, sc-19826), anti-SERCA2 (1:2500, sc-376235), and anti-GAPDH (1:3000, sc-32233) from Santa Cruz Biotechnology or β₁-AR (1:1000, ab3442, Abcam). All of them incubated at 4°C overnight. After incubation with appropriate secondary peroxidase-coupled antibodies for 1 h, immunodetection was carried out using enhanced chemiluminescence (Amersham Biosciences) followed by densitometric analysis with software ImageJ. Protein levels were expressed as a ratio of optical densities. GAPDH was used as a control for any variations in protein loading.

Histopathology Analyses

After experimental procedures, rats were anesthetized and euthanized by applying potassium chloride solution (KCl – 10%) into the jugular vein. The hearts were fixed in formalin (10%), embedded in paraffin and cut at 5 μm thickness followed by staining with hematoxylin-eosin. Morphometric analysis was performed using the software ImageJ. The mean nuclear area was extracted from each histological slide.

Neonatal Cardiomyocytes Culture

Rat neonatal cardiomyocytes (3-days old) were cultured as previously described (Rocha-Resende et al., 2012). Briefly, cardiac cells were plated in dishes containing M199 medium supplemented with 100 units/mL penicillin, 100 μg/mL streptomycin, 10% fetal bovine serum, and 2 mM/L L-glutamine. To prevent growth of fibroblasts, medium was supplemented with 20 μg/mL cytosine-D-arabino-furanoside (ARA-c). After 48 h, neonatal cardiomyocytes were exposed to isoproterenol

(10 μ M) and/or GBE (100 μ g/mL). When appropriated, cells were incubated with atropine (AT, 10 μ M) or N ω -nitro-L-arginine methyl ester hydrochloride (L-NAME, 10 μ M) for 48 h. Afterward, the cells were then used for immunofluorescence.

Immunofluorescence

Neonatal cardiomyocytes were fixed in a 4% paraformaldehyde solution and permeabilized with 0.5% Triton-X100. After blocking, cardiomyocytes plated onto glass coverslips were incubated for 1 h at room temperature with Alexa Fluor 488-conjugated anti-phalloidin (1:100, A12379, Invitrogen). Nuclear staining was obtained by incubating with 4,6-diamidino-2-phenylindole (DAPI, 1:50). Surface area of cardiomyocytes was measured in phalloidin stained cells. Images were acquired with a Zeiss LSM 510 confocal system located at Center of Acquisition and Processing of Images (CAPI-ICB, UFMG). All images were representative of two independent experiments in which multiple cells were evaluated.

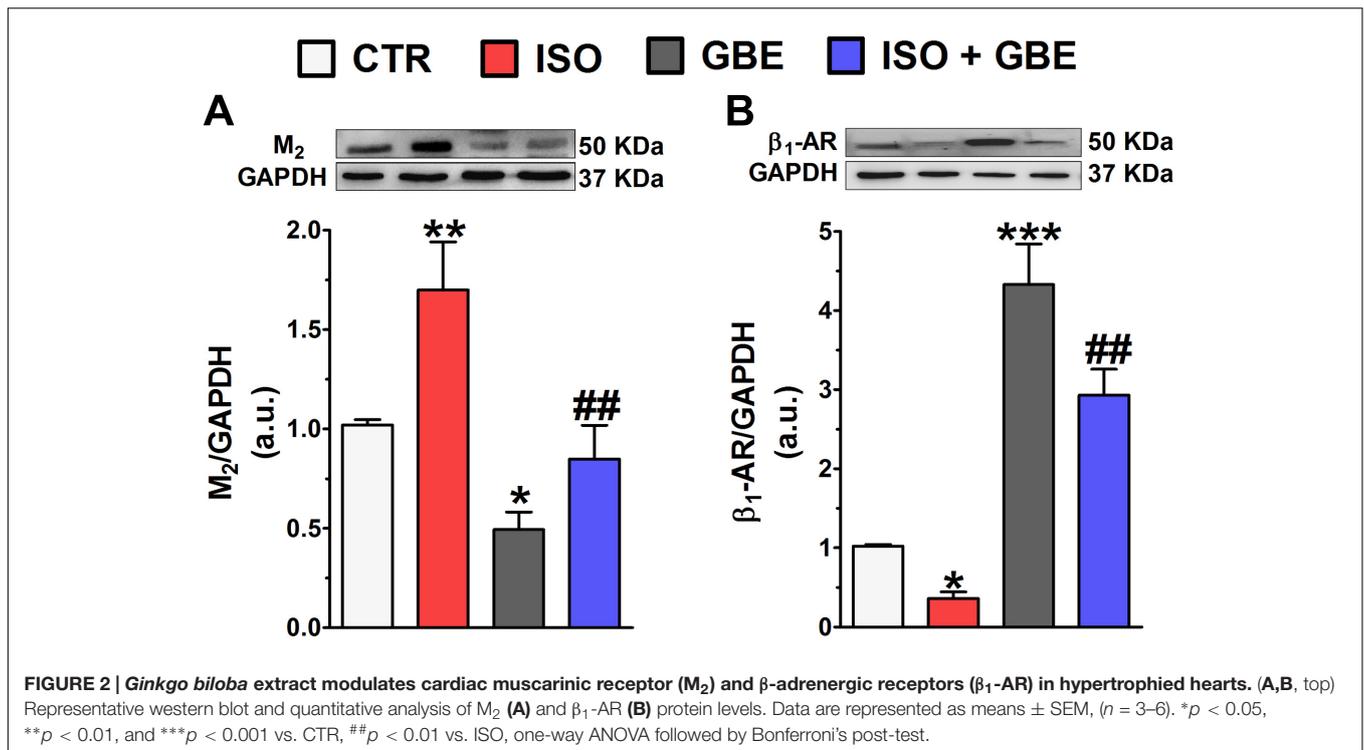

Statistical Analyses

All data are expressed as mean \pm SEM. Statistical comparisons were performed using GraphPad Prism 5.1 (San Diego, CA, USA). Normality and equality of variance were tested by Shapiro-Wilk and Levene test, respectively. Significant differences between groups were determined with one-way ANOVA followed by the Bonferroni *post hoc* test. Differences were considered to be statistically significant when $p < 0.05$.

RESULTS

Ginkgo biloba Extract Restores the Autonomic Imbalance of Isoproterenol-Treated Rats

First, we show that ISO-treated rats (4.5 mg/kg/day for 8 days) developed prominent cardiac hypertrophy, indicated by an

increase in heart weight to body weight or tibia length ratios compared with untreated rats. Remarkably, concomitant GBE treatment (100 mg/kg) prevented the cardiac hypertrophy induced by chronic β-AR stimulation (Table 1). *In vivo* evaluation of cardiovascular function demonstrated a decreased HR in ISO-treated rats, which was not prevented after GBE treatment. Despite a tendency toward lower mean arterial pressure in ISO group, there was no significant change when compared to untreated group (Table 2).

It is well known that chronic β-AR stimulation induces profound alterations in autonomic nervous system (Shivkumar and Ardell, 2016), therefore we next evaluated whether GBE modulates the autonomic balance and BRS of hypertrophic hearts. As expected, chronic β-AR treatment led to a greater power in the LF band (Figure 1A) and smaller power in the HF band (Figure 1B) when compared to control, an indication of sympathovagal imbalance. Notably, GBE treatment fully restored sympathovagal balance in ISO-treated rats (LF/HF ratio, Figure 1C). Moreover, as shown in Figure 1D ISO-treated rats displayed decreased spontaneous BRS, which was rescued by GBE treatment. Altogether, our data indicate that GBE treatment modulates the sympathovagal balance of ISO-treated rats, suggesting the involvement of the cholinergic parasympathetic drive in the restoration of autonomic balance mediated by GBE.

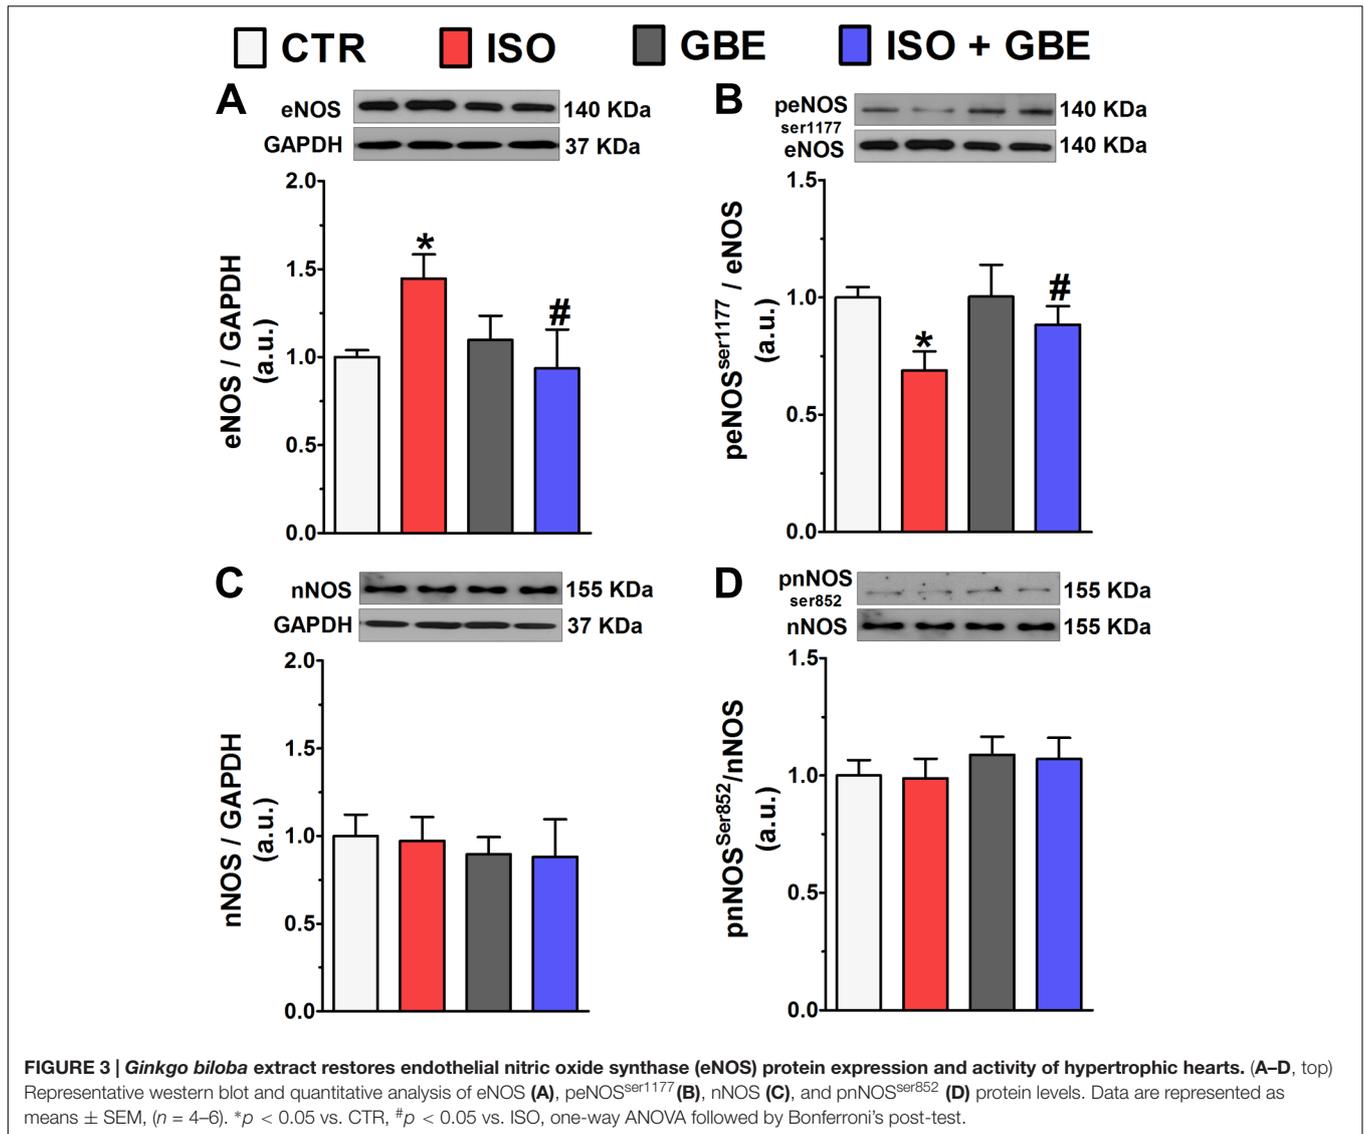

***Ginkgo biloba* Extract Prevents the Upregulation of Cardiac Muscarinic Receptor and Downregulation of β₁-AR Induced by Chronic β-AR Stimulation**

To investigate whether GBE modulates expression levels of muscarinic receptor (M₂) and β₁-AR in the heart, we next

performed the western-blot technique. As shown in the Figure 2, protein levels of M₂ were upregulated (Figure 2A), while the expression of β₁-AR was downregulated (Figure 2B) in left ventricles from ISO-treated rats when compared to control. On the other hand, GBE treatment alone led to a decreased expression of M₂ (Figure 2A), while the protein levels of β₁-AR was upregulated (Figure 2B). Importantly, GBE treatment was able to prevent alterations of M₂ and β₁-AR induced by ISO suggesting that under this condition appropriated autonomic balance was restored. Once again, this finding reinforces the idea that *G. biloba*-mediated cardioprotective actions involve the activation of cholinergic activity.

***Ginkgo biloba* Extract Restores eNOS Protein Expression and Activity of Hypertrophic Hearts**

It is well known that augmented local cholinergic activity leads to an increase in NO levels (Rocha-Resende et al., 2012). Therefore, in order to better understand whether the synthesis of NO is involved in cardioprotective actions of GBE, we next evaluated protein expression and activity of the constitutive NO synthesis (eNOS and nNOS) in the heart. As shown in the Figure 3A, ISO-treated rats presented an upregulation of eNOS, while its activity was markedly reduced (Figure 3B). In contrast, GBE treatment of ISO-treated rats fully restored eNOS levels and activity when compared to control. Importantly, neither nNOS expression nor activity was changed by ISO or GBE treatment (Figures 3C,D). Altogether,

our data show that GBE treatment restores impaired eNOS.

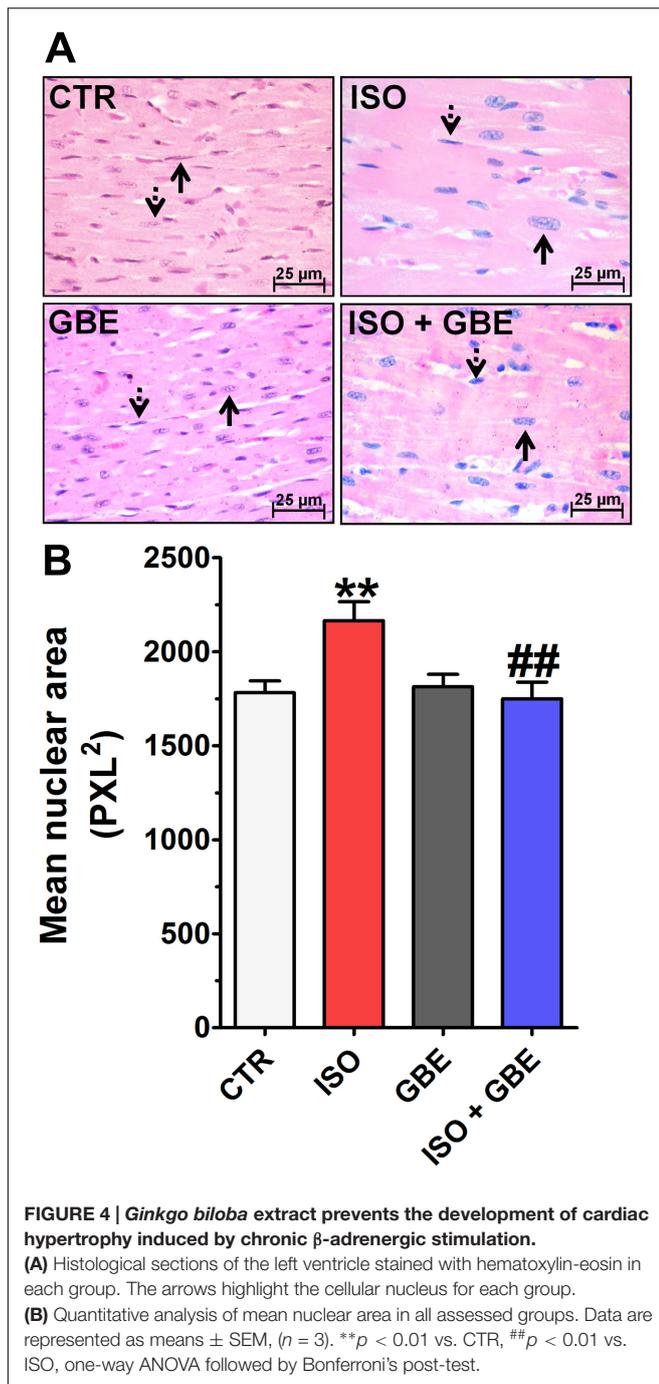

***Ginkgo biloba* Extract Prevents ISO Induced Hypertrophic Remodeling**

To confirm whether GBE treatment exhibits cardioprotection through impeding typical hypertrophic remodeling induced by chronic β -AR stimulation, morphometric analysis of nuclear cross-sectional area was evaluated. As shown in the Figure 4, left ventricular histological sections display increased nuclear area in ISO-treated rats, which was restored to the control condition with GBE treatment. GBE treatment alone had no effect on nuclear size. Moreover, ISO group showed areas that were characterized by intense spindle cell proliferation, identified as fibroblasts replacing the cardiac parenchyma (Figure 5). However, GBE treatment of ISO-treated rats exhibited markedly less expressive hypercellular areas, suggesting a minor

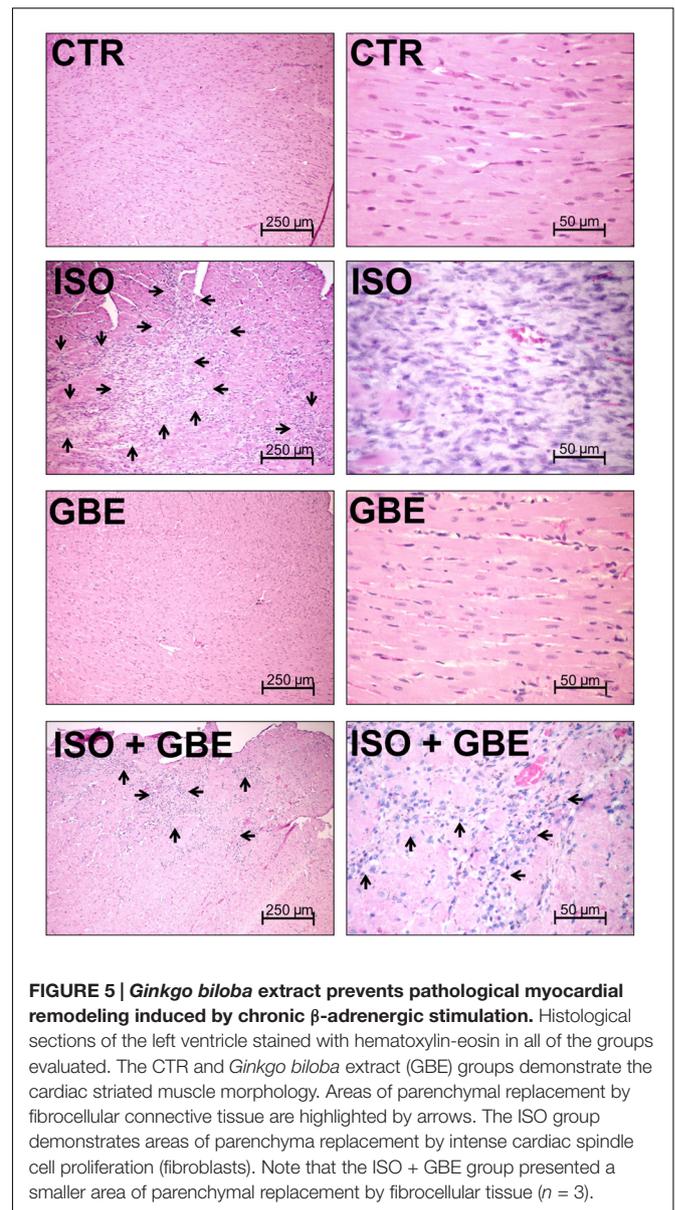

replacement of cardiac parenchyma and therefore, a considerable decrease in the degree of cardiac remodeling. GBE-treated group demonstrated a typical cardiac parenchyma similar to untreated group, suggesting that the administration of GBE did not promote remarkable changes in the histological architecture of the heart.

***Ginkgo biloba* Extract Prevents Electrocardiographic Changes and Restores the Impaired Left Ventricular Contractility Induced by Chronic β -AR Stimulation**

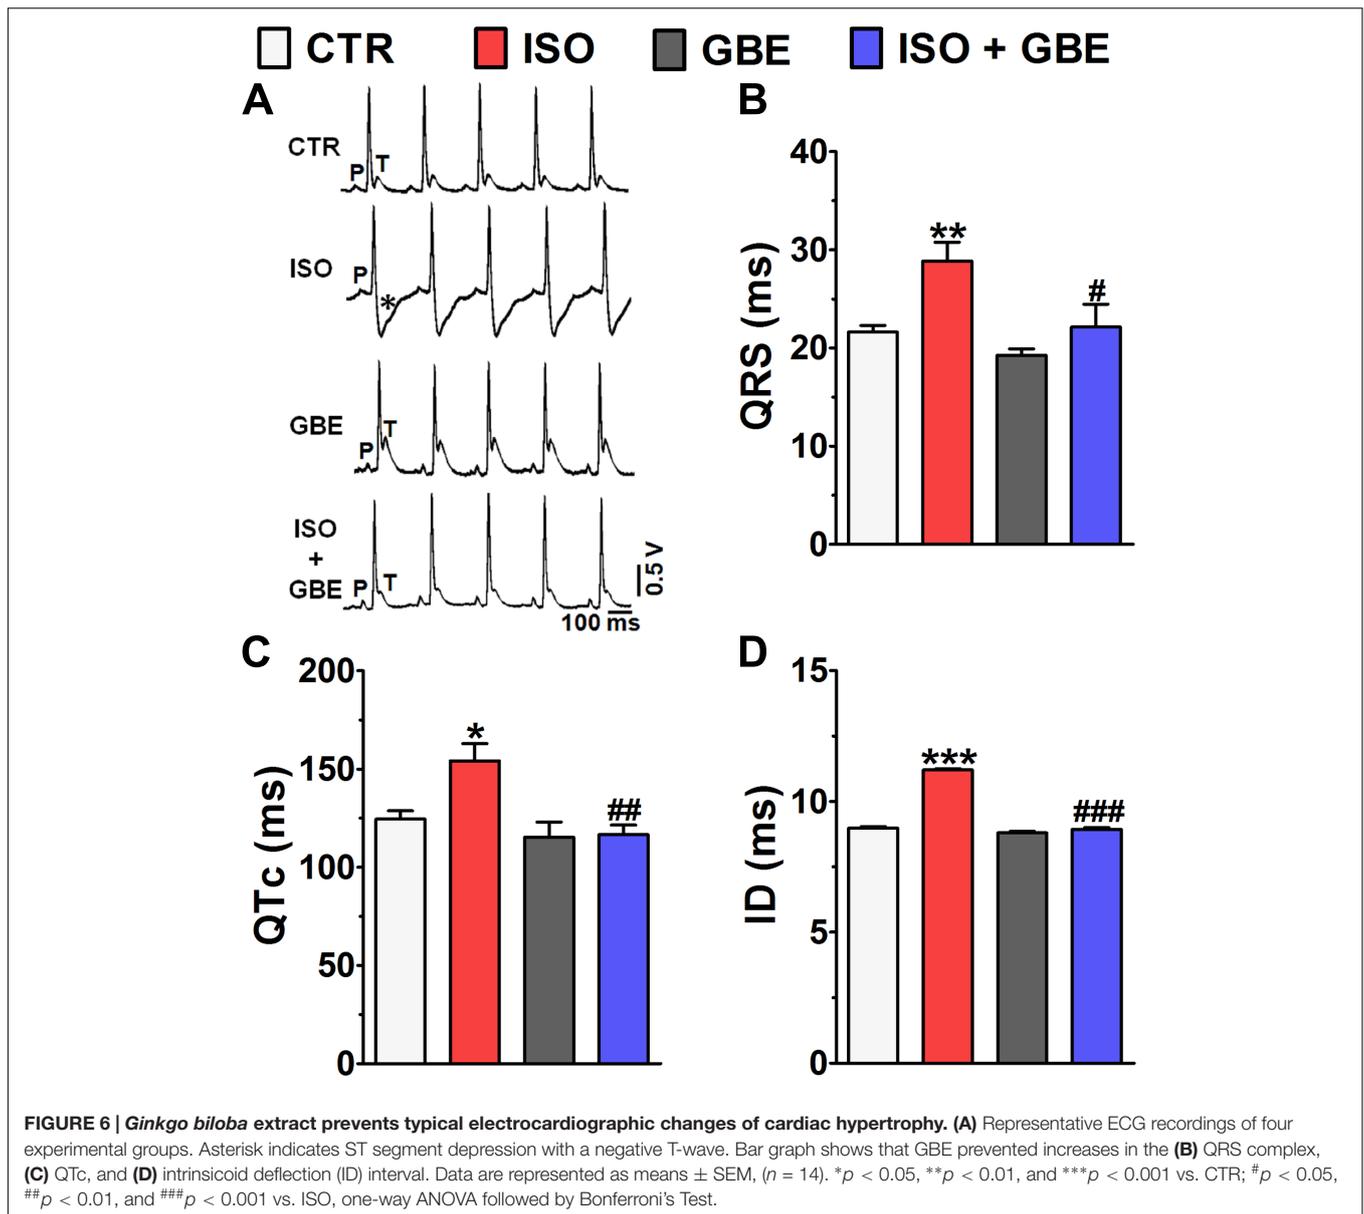

Maladaptive cardiac remodeling is commonly associated with myocardial electric remodeling, therefore we next assessed whether GBE treatment prevents such electrical dysfunction through surface ECG recordings. Figure 6A shows typical ECG tracing in four experimental groups. It worthwhile note

that depression of ST segment (negative T-wave) induced by chronic β -AR stimulation was abolished in GBE-treated rats. Moreover, rats that received ISO presented ECG changes that are typical of hypertrophic hearts such as, marked enlargement of QRS complex duration (Figure 6B), prolonged QTc interval (Figure 6C), and increased ID (Figure 6D) compared with control. Notably, concomitant treatment with GBE fully abolished all ECG changes found in ISO-treated rats (Figures 6A–C).

Impaired myocardial contractility is a hallmark of pathological ventricular remodeling, therefore we also assessed whether GBE prevents the loss of ventricular contractility through Langendorff-isolated heart Figure 7A. As shown in the Figure 7B, chronic β -AR stimulation markedly decreased the LVDP when compared with control group, whereas GBE treatment significantly ameliorated the contractile dysfunction of hypertrophied hearts. GBE treatment alone did not affect the LVDP. Furthermore, during heart perfusion, the coronary perfusion pressure was simultaneously recorded in order to evaluate the coronary vasomotor tone. Chronic β -AR stimulation led to a higher coronary pressure when compared with control, whereas GBE treatment fully abolished this effect (Figure 7C). Interestingly, animals that only received GBE showed a reduced coronary pressure compared to untreated rats.

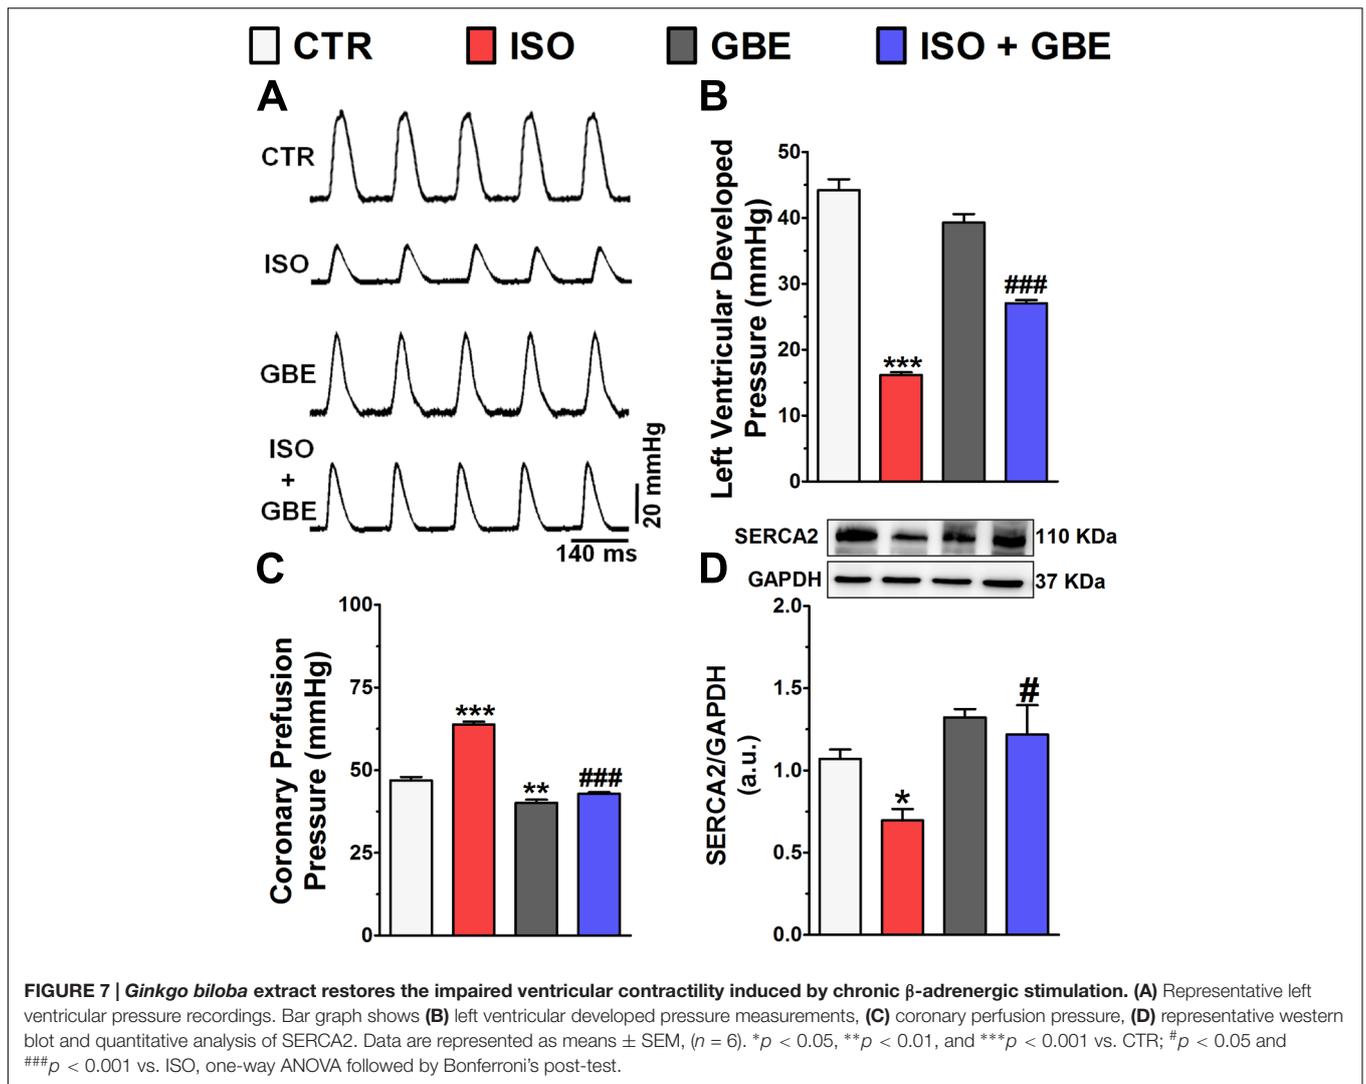

Abnormal Ca^{2+} handling is a common feature of impaired cardiac contractility, therefore it was evaluated the sarcoplasmic reticulum Ca^{2+} pump (SERCA2) expression in the heart. SERCA2 protein levels were significantly decreased in ventricles from ISO-treated rats compared to control (Figure 7D). In contrast, GBE treatment of ISO-treated rats fully restored the physiological levels of SERCA2.

Ginkgo biloba Extract Prevents Cardiomyocyte Hypertrophy via M_2/NO Pathway

Taken together, our data suggest that the cardioprotective action of GBE involves the activation of cholinergic signaling. Therefore,

to validate our findings, we next performed experiments on primary cultures of neonatal rat ventricular myocytes, which constitute a reliable *in vitro* model. Thus, in order to mimic the pathological conditions elicited by sustained β -AR stimulation, neonatal cardiomyocytes were treated with ISO and cellular hypertrophy was evaluated by measurement of myocyte surface area. As shown in the Figure 8, cardiomyocytes treated with ISO showed increased cell surface area, whereas co-treatment with GBE fully prevented this effect. Importantly, antihypertrophic action of GBE was abolished by atropine, a muscarinic receptor antagonist, or L-NAME, an inhibitor of NOS. Moreover, GBE alone had no effect on cellular area. Altogether, these data show that GBE antihypertrophic effect occurs *via* activation of M_2/NO pathway.

DISCUSSION

The results of the present study demonstrate that GBE counteracts the deleterious cardiac actions of sustained β -AR activation by preventing autonomic imbalance, myocardial remodeling, aberrant ECG waveforms, and ventricular dysfunction. In addition, our findings unravel the activation of M_2 /NO pathway as a new mechanism involved in the remarkable antihypertrophic action of GBE.

Sympathovagal imbalance is observed during the development of several cardiovascular diseases (Shivkumar and Ardell, 2016). Accordingly, abnormal vagal activity is found during the early stage of cardiac dysfunction, whereas enhanced cholinergic activity has been associated with decreased pathological cardiac remodeling and risk of developing life-threatening arrhythmia (Li et al., 2004; Sabino et al., 2013). Therefore, pharmacological compounds that improve the cholinergic activity appear as a promising alternative therapy for cardiovascular disorders. In line with this hypothesis, our *in vivo* data show that GBE

prevents the shift of cardiac autonomic balance toward a sympathetic drive and impaired baroreflex sensibility, as typically found in heart failure and hypertensive rats (Zucker et al., 1995; Botelho-Ono et al., 2011). Moreover, taking into account recent studies that have proposed the involvement of neuronal and non-neuronal cholinergic machinery in the protective effect against sustained β -AR stimulation (Rocha-Resende et al., 2012; Gavioli et al., 2014; Roy et al., 2016), in addition to the proposed cholinergic involvement in the GBE-mediated neuroprotection (Nathan, 2000; Kehr et al., 2012) we raised the hypothesis that GBE may promote cardioprotection against sustained β -AR stimulation *via* cholinergic pathway.

Stimulation of muscarinic receptors represents the primary trigger for activation of downstream intracellular signaling. Moreover, despite the well known five distinct muscarinic receptor subtypes (M_1 – M_5), M_2 receptor is the most abundant isoform in cardiomyocytes (Lara et al., 2010). Therefore, in the present study we focused on the M_2 receptor due to the

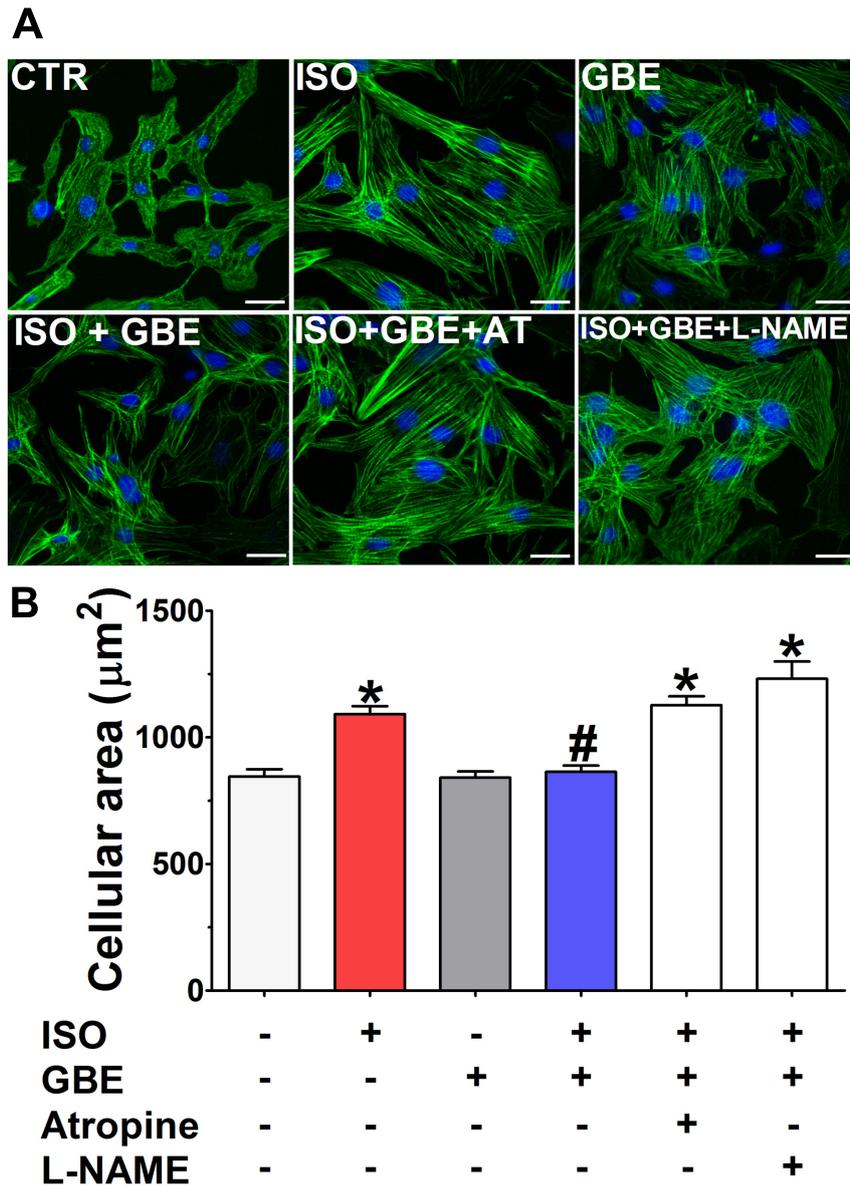

FIGURE 8 | *Ginkgo biloba* extract suppresses cellular hypertrophy induced by isoproterenol via M₂/NO pathway in rat neonatal cardiomyocytes. (A) Representative immunofluorescence images from phalloidin/DAPI stained neonatal cardiomyocytes in control (CTR), *Ginkgo biloba* extract (GBE, 100 μg/mL), isoproterenol (ISO, 10 μM), isoproterenol plus *Ginkgo biloba* extract (ISO + GBE), isoproterenol plus *Ginkgo biloba* extract and muscarinic receptor antagonist, atropine (ISO + GBE + AT), isoproterenol plus *Ginkgo biloba* extract and nitric oxide synthase inhibitor, L-NAME (ISO + GBE + L-NAME) treated cells. overwhelming expression in the heart. Here, we showed that M₂ receptor was upregulated by chronic β-AR administration. This result correlated with previous *in vivo* and *in vitro* findings obtained from ISO-stimulated cardiomyocytes (Rocha-Resende et al., 2012; Gavioli et al., 2014). Importantly, GBE treatment prevented this change, indicating attenuated β-AR stimulation and therefore, the upregulation of M₂ receptor was no longer required. Moreover, downregulation of β-AR has been consistently reported as a result of G protein-coupled receptor

kinases and β-arrestin activities (Noor et al., 2011). In the present study, GBE treatment alone led to a downregulation of M₂ and upregulation of β₁-AR. In fact, our findings are strikingly similar to data obtained *in vivo* with rats subjected to treatment with pyridostigmine, a cholinesterase inhibitor (Gavioli et al., 2014). Along with these lines, previous studies have reported the anticholinesterase activity of GBE (Stein et al., 2015; Kim et al., 2016). Although the exact mechanism by which GBE alters cholinergic signaling is still unknown, it is plausible to assume

that GBE acts, at least in part, through changes in cholinergic signaling.

Nitric oxide release has been reported as the downstream effector of cholinergic signaling in cardiomyocytes (Balligand et al., 1993; Rocha-Resende et al., 2012). Moreover, several studies have consistently demonstrated the beneficial actions of NO in the cardiovascular system by regulating eNOS and nNOS signaling pathways (Barouch et al., 2002; Ziolo et al., 2008; Umar and van der Laarse, 2009). *In vitro* and *in vivo* studies have shown that GBE enhances NO bioavailability (Sasaki et al., 2002; Koltermann et al., 2007). Accordingly, activation of NO signaling pathway by GBE treatment has been associated with cardioprotection in a model of ischaemia-reperfusion injury (Shen et al., 1998) and adriamycin-induced acute cardiotoxicity (El-Boghdady, 2013). In accordance with previous studies, we showed that despite increased eNOS expression in response to chronic β -AR stimulation (Champion et al., 2004; Krennek et al., 2009), its activity was markedly decreased, what would lead to reduced NO bioavailability (Victorio et al., 2016). The remarkable restoration of expression and impaired eNOS activity induced by GBE treatment of isoproterenol rats indicates eNOS-mediated NO as a negative modulator of chronic β -AR stimulation (Ozaki et al., 2002). Although recognized as a therapeutic target for several cardiovascular diseases (Zhang et al., 2014), in the present study, we showed that nNOS expression and activity remained unchanged upon chronic β -AR stimulation. Thereby these data rule out a significant contribution of nNOS-mediated NO in the antihypertrophic effect of GBE. Altogether, our data is the first evidence on the involvement of NO signaling pathway in the antihypertrophic effect of GBE.

Our data also endorse previous studies that correlate the diffuse myocardial damage characterized by fibroblast replacement with aberrant electrical remodeling (Tomaselli and Marban, 1999; Chapman et al., 2001). Here, we show that GBE treatment prevented the pathological remodeling and ECG changes induced by chronic β -AR stimulation. Accordingly, reduced myocardial fibrosis induced by ligation of left anterior descending artery has been reported in GBE-treated rats. In this model, GBE treatment decreased expression levels of transforming growth factor- β 1, and matrix metalloproteinase 2 and 9, therefore attenuating the extracellular matrix deposition (Li et al., 2015). The late-phase of hypertrophic remodeling is also associated with abnormalities in the Ca^{2+} handling, in which contributes to ventricular dysfunction (Bers et al., 2003; Lang et al., 2015). Altogether, our data indicate the GBE attenuates the decrease of ventricular wall compliance and increase of stiffness, thereby ameliorating the ventricular dysfunction. In addition, decreased expression of the SERCA2 was found in ISO-treated rats. This finding is consistent with reduced sarcoplasmic reticulum Ca^{2+} load, already described during cardiac hypertrophy stage, thereby affecting SR Ca^{2+} refilling and, consequently, ventricular contractility (Bers et al., 2003; Gavioli et al., 2014). Therefore, restoration of SERCA2 levels in GBE-treated rats represents an important underlying mechanism involved in the ventricular dysfunction amelioration.

β -adrenergic receptors are also expressed on the endothelial and smooth muscle cells and, its actions seems to be dependent of the vascular bed and isoforms (Flacco et al., 2013). In resistance artery, chronic β -AR stimulation leads to impaired vascular tone (Davel et al., 2006), increased expression of proinflammatory cytokines and NF- κ B activity (Davel et al., 2008), and decreased NO bioavailability (Victorio et al., 2016). Accordingly, in the present study, we demonstrated that chronic β -AR stimulation caused a marked increase in the coronary resistance, which was fully prevented by GBE treatment. Moreover, we showed the rats treated with GBE displayed lower coronary perfusion pressure. Supporting our findings, the vasodilator activity of GBE was previously demonstrated in rat aorta rings through opening of Ca^{2+} -activated potassium channel, in which ultimately causes endothelial cell hyperpolarization and NO release by eNOS activity (Sato and Nishida, 2004).

Although our data indicate that GBE treatment counteracts the deleterious cardiac actions of sustained β -AR stimulation *via* cholinergic pathway, we unequivocally validated our hypothesis through *in vitro* experiments. Accordingly, we showed the antihypertrophic action of GBE was fully abolished by either, muscarinic receptor or NOS inhibition. Indeed, the downstream cascade of muscarinic pathway involves the activation of NOS and, consequently, NO release (Rocha-Resende et al., 2012). Consistent with our data, previous study demonstrated that similar dose of GBE (100 $\mu\text{g}/\text{mL}$) enhanced NO production by increasing eNOS activity in endothelial cells (Koltermann et al., 2007). Moreover, it is worthy of note that the *in vitro* concentration used in the present study was determined in accordance with pharmacokinetics studies in human that have demonstrated this concentration is likely to be achieved in the blood after daily intake of 80–240 mg, which represents the regular dosage of GBE for effective therapy (Biber, 2003; Ude et al., 2013). Altogether, our results bring new insights into the mechanism involved in the antihypertrophic action of GBE, which goes beyond its antioxidant activity.

CONCLUSION

In summary, our data show that the deleterious cardiac actions of sustained β -AR activation were significantly attenuated by GBE treatment. Furthermore, our findings indicate that pharmacological actions of GBE treatment alone on sympathetic-cholinergic receptors may be involved in the cardioprotective effect. Accordingly, we show that the antihypertrophic action of GBE occurs *via* activation of M_2/NO pathway. Overall, these findings uncover a new mechanism involved in the cardioprotective action of GBE.

AUTHOR CONTRIBUTIONS

TM and IdJ participated in all steps of this study. JdS, GdA, FM, RdS, JdM-F, RM-d-S, PM, SS, and RP-F performed experiments. CdV, SG, VS-F, RA-J, and SL-S contributed to the experimental design, data analyses, data interpretation, and the preparation and revision of the manuscript.

FUNDING
