Physiol.* 10:1216. doi: 10.3389/fphys.2019.01216

Muscle regeneration is a complex process governed by the interplay between several muscle-resident mononuclear cell populations. Following acute or chronic damage these cell populations are activated, communicate via cell–cell interactions and/or paracrine signals, influencing fate decisions via the activation or repression of internal signaling cascades. These are highly dynamic processes, occurring with distinct temporal and spatial kinetics. The main challenge toward a system level description of the muscle regeneration process is the integration of this plethora of inter- and intracellular interactions. We integrated the information on muscle regeneration in a web portal. The scientific content annotated in this portal is organized into two information layers representing relationships between different cell types and intracellular signaling-interactions, respectively. The annotation of the pathways governing the response of each cell type to a variety of stimuli/perturbations occurring during muscle regeneration takes advantage of the information stored in the SIGNOR database. Additional curation efforts have been carried out to increase the coverage of molecular interactions underlying muscle regeneration and to annotate cell–cell interactions. To facilitate the access to information on cell and molecular interactions in the context of muscle regeneration, we have developed Myo-REG, a web portal that captures and integrates published information on skeletal muscle regeneration. The muscle-centered resource we provide is one of a kind in the myology field. A friendly interface allows users to explore, approximately 100 cell interactions or to analyze intracellular pathways related to muscle regeneration. Finally, we discuss how data can be extracted from this portal to support *in silico* modeling experiments.

**Keywords:** muscle regeneration, bioinformatics resource, cell interactions, pathways in muscle regeneration, muscle regeneration database, cell signaling

## INTRODUCTION

Tissue homeostasis and repair after damage, are complex processes finely regulated by the interactions between different cell types exchanging signals that, in turn, stimulate intracellular signaling cascades. These orchestrated processes have been extensively studied over the past decades (Bentzinger et al., 2013; Rojas-Ríos and González-Reyes, 2014; Goichberg, 2016). However, the relevant information is dispersed in the bio-medical literature and scientists face the problem of designing experiments and interpreting results in the context of scattered and poorly organized

prior knowledge. Although our understanding of regeneration processes is far from complete, the progress in the field would benefit from the assembly of models that take into account most of the available information. To address this issue, we conceived a web resource to organize prior knowledge about muscle regeneration processes in a structured and easily accessible format.

The adult skeletal muscle is a rather stable tissue, characterized by a relatively low cell turnover in physiological conditions (Rojas-Ríos and González-Reyes, 2014). At the same time, it is remarkably dynamic and plastic and is capable of fast recovery and healing following damage caused by exercise, immobilization or chemically induced injury (Tedesco et al., 2010; Bentzinger et al., 2013; Judson et al., 2013; Ceafalan et al., 2014; Fu et al., 2015). Complete repair after damage is mediated by the regeneration process which involves the collaborative cross-talk between cells of the immune system, Fibro/Adipogenic Progenitors (FAPs) and satellite cells (SCs), among others (Bentzinger et al., 2013; Tidball, 2017).

Following injury, muscle regeneration is organized into two closely interdependent phases, eventually leading to the formation of new myofibers. An initial pro-inflammatory wave triggers the recruitment of mast cells, neutrophils and monocyte/macrophage to the injury site. These cells coordinate the clearance of cellular and tissue debris, while secreting pro-inflammatory cytokines and growth factors stimulating SC proliferation and self-renewal (Bentzinger et al., 2013). At a later stage, an anti-inflammatory phase stimulates SCs to differentiate into myoblasts, which in turn fuse to form myotubes and myofibers, thus restoring the tissue architecture (Cornelison, 2018).

The process is regulated in time and space and the different cell types are recruited and/or activated with distinct temporal kinetics. Myopathies and aging, interfere with this finely regulated process causing a decrease of the regeneration potential and the disruption of muscle structural organization (Uezumi et al., 2014).

To summarize, the experimental information related to muscle regeneration is complex, diverse and sparse. Defining a strategy to combine this information in an integrated picture represents a major task. Here, we present Myo-REG, a repository of data related to muscle regeneration that was developed to meet this challenge. Myo-REG aims at capturing information on the mechanisms underlying the regeneration process of the skeletal muscle tissue. The manually curated literature-based information is organized in a structured format and offered to the user via a friendly and intuitive interface.

Myo-REG allows users to browse a variety of data types through a single platform at <https://myoreg.uniroma2.it>. The stored information is annotated by manually mining the literature or by automatically capturing information from other online resources.

Myo-REG is built on two major information layers: the cell–cell interactions and the molecular interactions. Cell–cell interactions include both direct physical contacts between cells and relationships mediated by secreted signaling molecules. The molecular layer integrates physical and causal relationships that

support the propagation of signals in the different cell types. The portal content can be explored starting from a cell interaction map offering an entry point for looking into both cell and signaling interactions.

## MATERIALS AND METHODS

### Data Model

Cell–cell and causal protein interactions were captured via an extensive literature search supported by text mining. To improve the consistency of the data and to make the annotations exchangeable with other resources, whenever available, we used external identifiers (IDs) for both cell and molecular entities. Since cell types are not uniquely defined and are often heterogeneous, delineating the cells that are involved in muscle regeneration required some blunt decisions by the curators. This, sometimes, is the result of a compromise between alternative opinions. Cell identifiers are annotated according to the definition in the Cell Ontology section of Ontobee (Ong et al., 2017). Not all the cell types that we have considered in our model have a definition and an identifier in Ontobee. Whenever this was the case, we adopted an internal Myo-REG identifier (**Supplementary Table S1**). In addition, we used UniProt IDs (The UniProt Consortium, 2017), ChEBI IDs (Hastings et al., 2016), for proteins and chemicals, respectively and SIGNOR IDs (Perfetto et al., 2016) for, phenotypes and protein complexes.

For effective usage of the stored information, interaction annotation must be based on clearly defined ontologies. This issue has been recognized since long by the molecular interaction community that, within the PSI-MI initiative, has defined ontologies that have guided the annotation of protein interaction information in Myo-REG (Perfetto et al., 2018; Sivade et al., 2018). On the other hand, no community defined standard for cell interactions has yet been agreed upon. Thus, we developed a cell interaction ontology which is based on Gene Ontology terms (Ashburner et al., 2000; The Gene Ontology Consortium, 2019) and describes the interaction mechanisms that are considered in our cell interaction model. We took into consideration both differentiation mechanisms (e.g., FAPs differentiate into adipocytes) or stimulation/inhibition mechanisms mediated either by direct cell contact or by secretion of cytokines that target a particular cell type (e.g., eosinophils secrete IL-4 to activate FAPs).

A classical logic model does not allow representing relations of the type, for instance, “TNF $\alpha$  inhibits FAP adipogenesis,” where adipogenesis is not a node but rather a differentiation edge between FAPs and adipocytes. Thus, in these “transition/differentiation” edges we introduced a *virtual* transition node (i.e., FAPs  $\rightarrow$  adipocytes) allowing to represent that some stimuli might impact on the process.

### Annotations

Cell–cell and causal protein interactions were captured by an extensive literature survey. In summary, each entity relationship stored in the database is annotated with the ID of the interacting cells, the relation mechanism, the PubMed

ID of an article presenting experimental information that support the interaction and a representative sentence extracted from the same article. Although in the annotation we have retained the information about the organism where any given relationship was shown experimentally, the protein nodes in the Myo-REG signaling network are mapped to the human proteome, irrespective of the organism used to demonstrate the interaction.

Biomarkers for each cell type were selected for their relevance in the context of muscle regeneration scientific literature. This was decided after consulting relevant reviews (Bentzinger et al., 2013; Tedesco et al., 2017; Wosczyzna and Rando, 2018) describing the specific biomarkers that characterize the distinct cell types. Since biomarkers of the same cell type may differ in human and mouse, we have annotated two different biomarker tables.

## Generation of Boolean Models

Deriving Boolean models from causal networks implies associating to each node of the network a Boolean function stating how the node value changes according to the values of the upstream nodes. However, this operation requires establishing logic gates governed by the operators *AND*, *OR* or *NOT* to describe how two or more inputs combine to produce a single input. However, this information is not contained in causal networks and often the experimental information that is necessary to define logic gates is not available. As a consequence, the algorithm that we have implemented to translate the causal information into Boolean logic is based on the following *ad hoc* rules:

- The formation of a complex is associated to an *AND* operator (e.g., “nodeAB = nodeA *AND* nodeB”). The complex subunits must all be “True” for the complex to be formed.
- Inhibitions are assumed to dominate over activations. If nodeC is activated by nodeA and inhibited by nodeB, this is translated with an *AND NOT* operator (“nodeC = nodeA *AND NOT* nodeB”).
- In establishing all the remaining updating rules, two incoming signals are combined with the *OR* operator (e.g., “nodeC = nodeA *OR* nodeB” if node C is activated by both nodeA and nodeB).
- When more inhibitions are present, inhibitors are combined with an *OR* operator [e.g., “nodeC = *NOT* (nodeA *OR* nodeB)”].

Although these assumptions often accurately describe biological interactions, they are arbitrary and may turn out to be incorrect in some cases. Whenever additional experimental information is available, the integration of activating and inactivating inputs should be evaluated critically and the corresponding logic gates edited accordingly in order to obtain a more accurate model.

## Resource Backbone

The resource informatics-backbone is encoded in PHP<sup>1</sup> and JavaScript<sup>2</sup> and the page styles are implemented with CSS<sup>3</sup>. The database management system is PostgreSQL<sup>4</sup> that is object-relational and has a high standard compliance.

Cell–cell interaction graphs are laid out with cytoscape.js (Franz et al., 2016), a graph library written in JavaScript that allows the assembly of graphs based on entity nodes (cells and proteins) and edges (interactions among entities), including annotations for nodes and edges. Molecular interactions are displayed via the SIGNOR graph viewer (Calderone and Cesareni, 2018), which allows a compartmental visualization of molecular entities as a signed directed graph.

## FAPs Isolation, Culture Conditions and Treatments

*Mdx* FAPs were isolated as Cd31-/Cd45-/α7-integrin-/Sca1 + cells, as described in Reggio et al. (2019b). Briefly, muscle hind limbs were dissected and minced in HBSS supplemented with 1% Penicillin-Streptomycin (P/S) and 0.2% BSA. The homogeneous tissue preparation was enzymatically digested in the presence of calcium and magnesium (Gibco, catalog 14040) with a mix of collagenase A (2 μg/ml) (Sigma-Aldrich, catalog 11088793001), Dispase II (2.4 U/ml) (Roche, catalog 04942078001) and DNase I (10 μg/ml) (Sigma-Aldrich, catalog 11284932001) for 1 h at 37°C. Single-cell suspension underwent progressive filtration before sorting. FAPs were purified from mdx mouse muscles using magnetic sorting via the MACS purification system (Miltenyi). Muscle mononuclear cells were resuspended in Magnetic Beads Buffer (MBB, 0.2% BSA, 2 mM EDTA in PBS 1×) and filtered through a 30 μm Pre-Separation Filter (Miltenyi Biotec, catalog 130-041-407). The single-cells were incubated in MBB with anti-CD31 microbeads mouse (Miltenyi Biotec, catalog 130-097-418) and anti-CD45 microbeads mouse antibodies (Miltenyi Biotec, catalog 130-052-301). Labeled cells were positively selected through the MS column (Miltenyi Biotec, catalog 130-042-201) depleting the CD31/CD45-fractions. Subsequently, the negative lineage was resuspended in MBB and incubated with mouse anti α7-integrin microbeads (Miltenyi Biotec, catalog 130-104-261). Finally, unlabeled cells were incubated with anti-Sca1 mouse microbeads (Miltenyi Biotec, catalog 130-106-641) and positively selected as Sca1-positive FAP cells. The sorting and labeling procedures using the micro-beads conjugated antibodies were performed according to the manufacturer's recommendations.

Fibro/adipogenic progenitors were resuspended in growth medium (GM) (20% FBS, 10 mM Hepes, 1 mM sodium pyruvate, 100 U/ml P/S in high glucose DMEM GlutaMAX™) and seeded at a cell density of  $4 \times 10^4$  cell/well. Two days after plating, the GM was refreshed and cells cultured with differentiation media. The adipogenic differentiation was

<sup>1</sup><http://php.net/docs.php>

<sup>2</sup><https://www.javascript.com/>

<sup>3</sup><https://www.w3.org/>

<sup>4</sup><https://www.postgresql.org/>

induced by incubating FAPs with adipocyte differentiation medium (ADM) obtained by adding 1  $\mu\text{g/ml}$  human recombinant insulin, 0.5 mM 3-isobutyl-1-methylxanthine (IBMX) and 1  $\mu\text{M}$  dexamethasone to GM. Two days after treatment cell were cultured for three additional days in adipocyte maintenance medium (AMM: GM + 1  $\mu\text{g/ml}$  insulin). Fibrogenic differentiation was induced by incubating FAPs with 5 ng/ml of human recombinant transforming growth factor- $\beta$  (TGF $\beta$ ) in 20% FBS for 2 days, followed by 3 days in 20% FBS medium. Adipogenic/fibrogenic co-treatment was performed by incubating FAPs in ADM containing TGF $\beta$  for 2 days, followed by 3 days in AMM.

## Immunofluorescence

Cells were fixed in 2% PFA for 10 min at RT and permeabilized in 0.5% Triton X-100, followed by saturation of non-specific binding sites with blocking solution (10% FBS, 0.1% Triton X-100 in PBS 11 $\times$ ) for 1 h at RT. Primary antibody ( $\alpha$ -SMA) was diluted in blocking solution and incubated for 1 h at RT. Cells were washed four times with 0.1% Triton X-100 in PBS 1 $\times$  and incubated for 30 min at RT with anti-mouse secondary antibody diluted in blocking solution. Cells were washed four times with 0.1% Triton X-100 in PBS, stained with Oil Red O and counterstained for 5 min at RT with 1 mg/ml Hoechst 33342 in 0.1% Triton X-100 in PBS 1 $\times$ .

## Oil Red O Staining

Oil Red O (Sigma Aldrich, catalog O0625) solution was prepared according to the manufacturer's recommendations. Fixed cells were washed twice in PBS 1 $\times$  and incubated for 10 min with the staining solution (Oil Red O with ultra-pure water in a 3:2 ratio). Stained cells were washed three times with 1 $\times$  PBS and counterstained using Hoechst 33342. Oil Red O stained cells were acquired via fluorescence microscopy.

## Images Acquisition and Analysis

Immunofluorescent images were automatically acquired via a LEICA fluorescent microscope (DMI6000B). Twenty images per well were acquired at 20 $\times$  magnification.

## Cell Differentiation Measurements and Statistical Analysis

Adipogenic differentiation of FAPs was estimated using ImageJ by counting the number of adipocytes (ORO-stained) normalized over the total number of nuclei per field. 20 fields were analyzed for each treatment at 20 $\times$  magnification. Fibrogenic differentiation was assessed using ImageJ by estimating the SMA-stained area for each field (expressed in pixels). 20 fields were analyzed for each treatment at 20 $\times$  magnification. Statistical significance was measured using the Kruskal–Wallis non-parametric test for multiple comparisons of independent groups, with significance values reported as follows: \* $p < 0.05$ ; \*\* $p < 0.01$ ; \*\*\* $p < 0.001$ . Statistical analyses were performed using R software.

## Single Cell RNA Sequencing Data Preprocessing

Single cell RNA sequencing (scRNAseq) data were retrieved from *Tabula muris* project (Tabula Muris Consortium et al., 2018). Specifically, microfluidic droplet-based 3'-end counts have been used for our analysis. Data have been re-processed with the Seurat package (Butler et al., 2018). Briefly, data have been log normalized and the 2000 most variable features used for downstream analysis. After scaling the data, we run principal component analysis (PCA) and used the first 10 components for dimensionality assessment (**Supplementary Figure S1A**). We then run the *t*-distributed stochastic neighbor (tSNE) algorithm to cluster cells and used the Myo-REG biomarkers, whenever possible, to assign cell identity to each cluster (**Supplementary Figures S1B,C**). B-lymphocyte and Scx + cell populations were characterized by the use of biomarkers reported by Giordani et al. (2019). tSNE plots reporting the expression of 15001 genes were loaded in Myo-REG. Expression levels of each gene is displayed as RNA counts in a gray-blue-red scale (from lowest to highest expression) with 200 bins.

## RESULTS

As for many complex and dynamic biological processes, muscle regeneration can be better described by multilevel modeling (Maus et al., 2011). In this approach, interactions between cell populations in the healing tissue and activation of pathways in the different cell types denote different levels of an organizational hierarchy. Each level has its own dynamics, usually faster for molecular than for cell interactions, which are integrated by multi-level modeling to describe the behavior of the whole system.

## Resource Data-Types and Organization

The two interaction types, cell–cell and signaling interactions, are captured from the literature by manual or automatic methods (Orchard et al., 2012; Müller et al., 2018). However, being conceptually different, the two interaction types require different ontologies for annotation and data structures for organization. Few resources exist to annotate and store cell interactions, and several online databases, such as KEGG (Kanehisa et al., 2017), Reactome (Fabregat et al., 2016), and SIGNOR (Perfetto et al., 2016), annotate pathway-related literature information. However, they are not focused on muscle regeneration, and filtering information relevant to myologists is not straightforward.

In addition, other data types that are relevant for modeling the muscle system, such as, modulation of gene expression, are stored in generalist resources (Edgar et al., 2002; Parkinson et al., 2007), making data integration a complex task. Myo-REG aims at capturing all these information layers, in order to integrate the relevant data into a resource that can be easily explored.

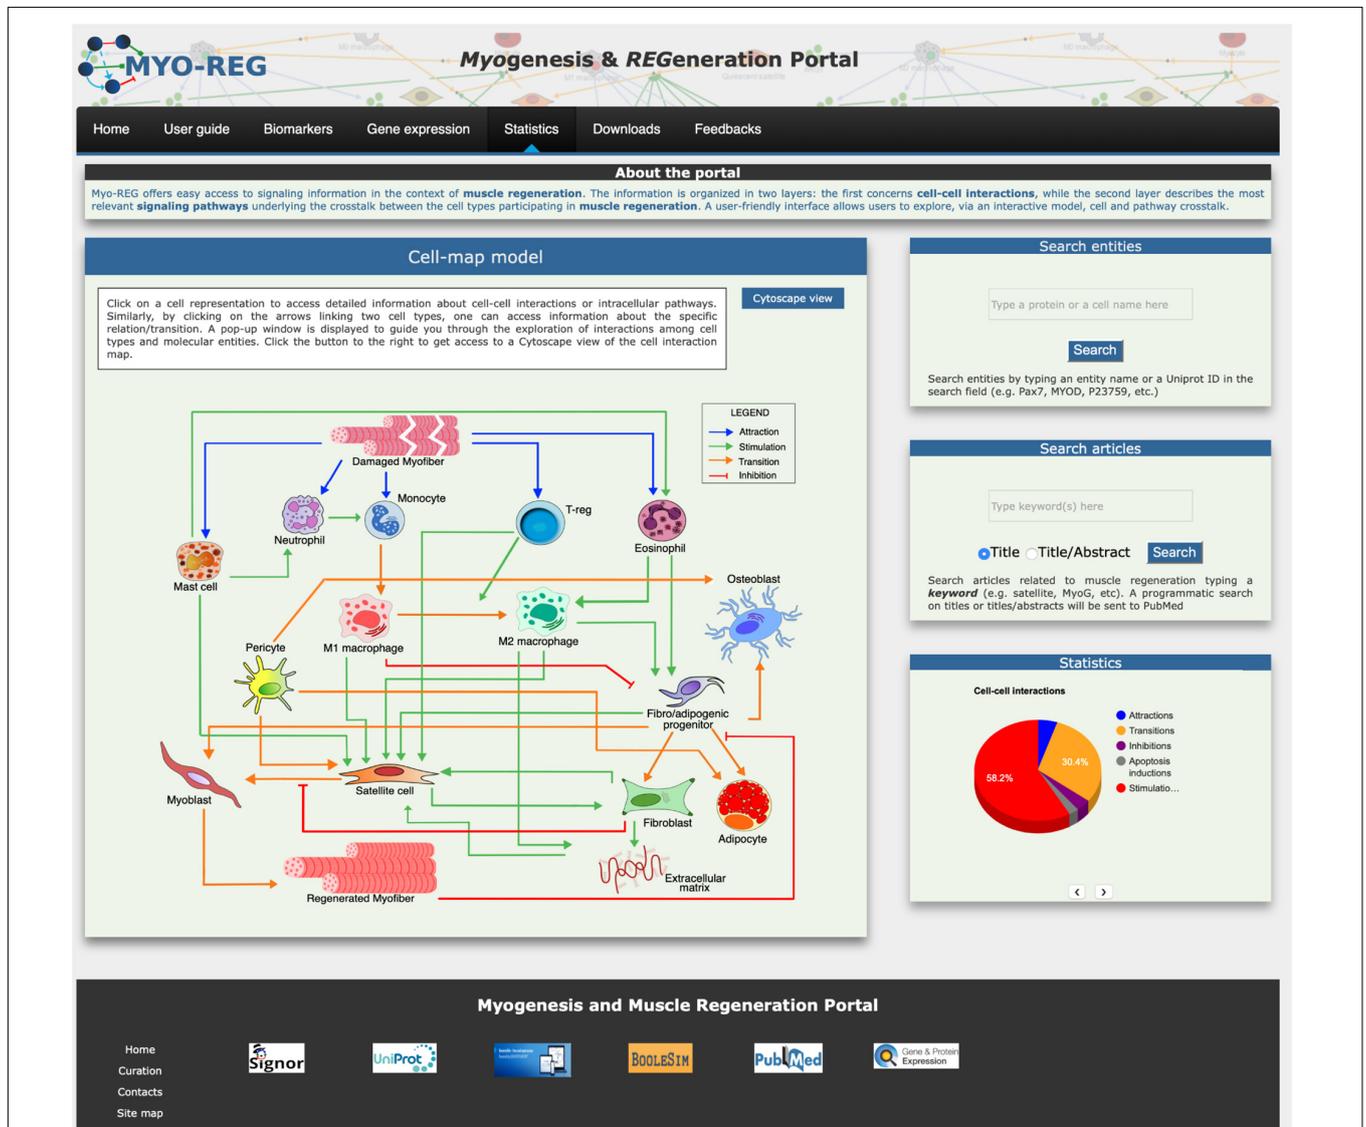

The core of the Myo-REG data structure consists of two layers each describing interactions between different biological entities. The two-layered organization allows users to explore both cellular and molecular interactions. In the first layer entities are cells

or secreted molecules that cells use to communicate (cytokines, growth factors and other signaling molecules). Cell interactions are defined as those relations in which either the source or the target entity is a cell, as defined in **Supplementary Table S1**. In Myo-REG cell interactions can be displayed as a static graph (diagram in the homepage) (**Figure 1**)<sup>5</sup> or as interactive view via a Cytoscape web application that can be accessed by clicking the “Cytoscape view” button in the home page (Franz et al., 2016). This latter representation also shows the cytokines that mediate the interactions between the cell types. In both displays, transitions (differentiations), stimulations or inhibitions are represented in different colors for a clearer interpretation.

<sup>5</sup><https://myoreg.uniroma2.it/>

Differently from the graph view in the homepage, the Cytoscape representation is editable. Each node can be moved around for a clearer display or clicked to expand the graph to visualize the entity first neighbors. Users are also offered the possibility to remove nodes from the rendered graph. All the relationships, displayed graphically via Cytoscape, are also reported in a table format at the bottom of the page.

The second layer annotates the molecular interactions, occurring inside the different cell types in response to external stimuli. Only relationships that are deemed relevant to muscle regeneration are considered. Differently from other signaling database, such as Reactome, that uses a reaction-based model, signaling relationships in Myo-REG are represented as causal relationships. According to this model signaling molecules are

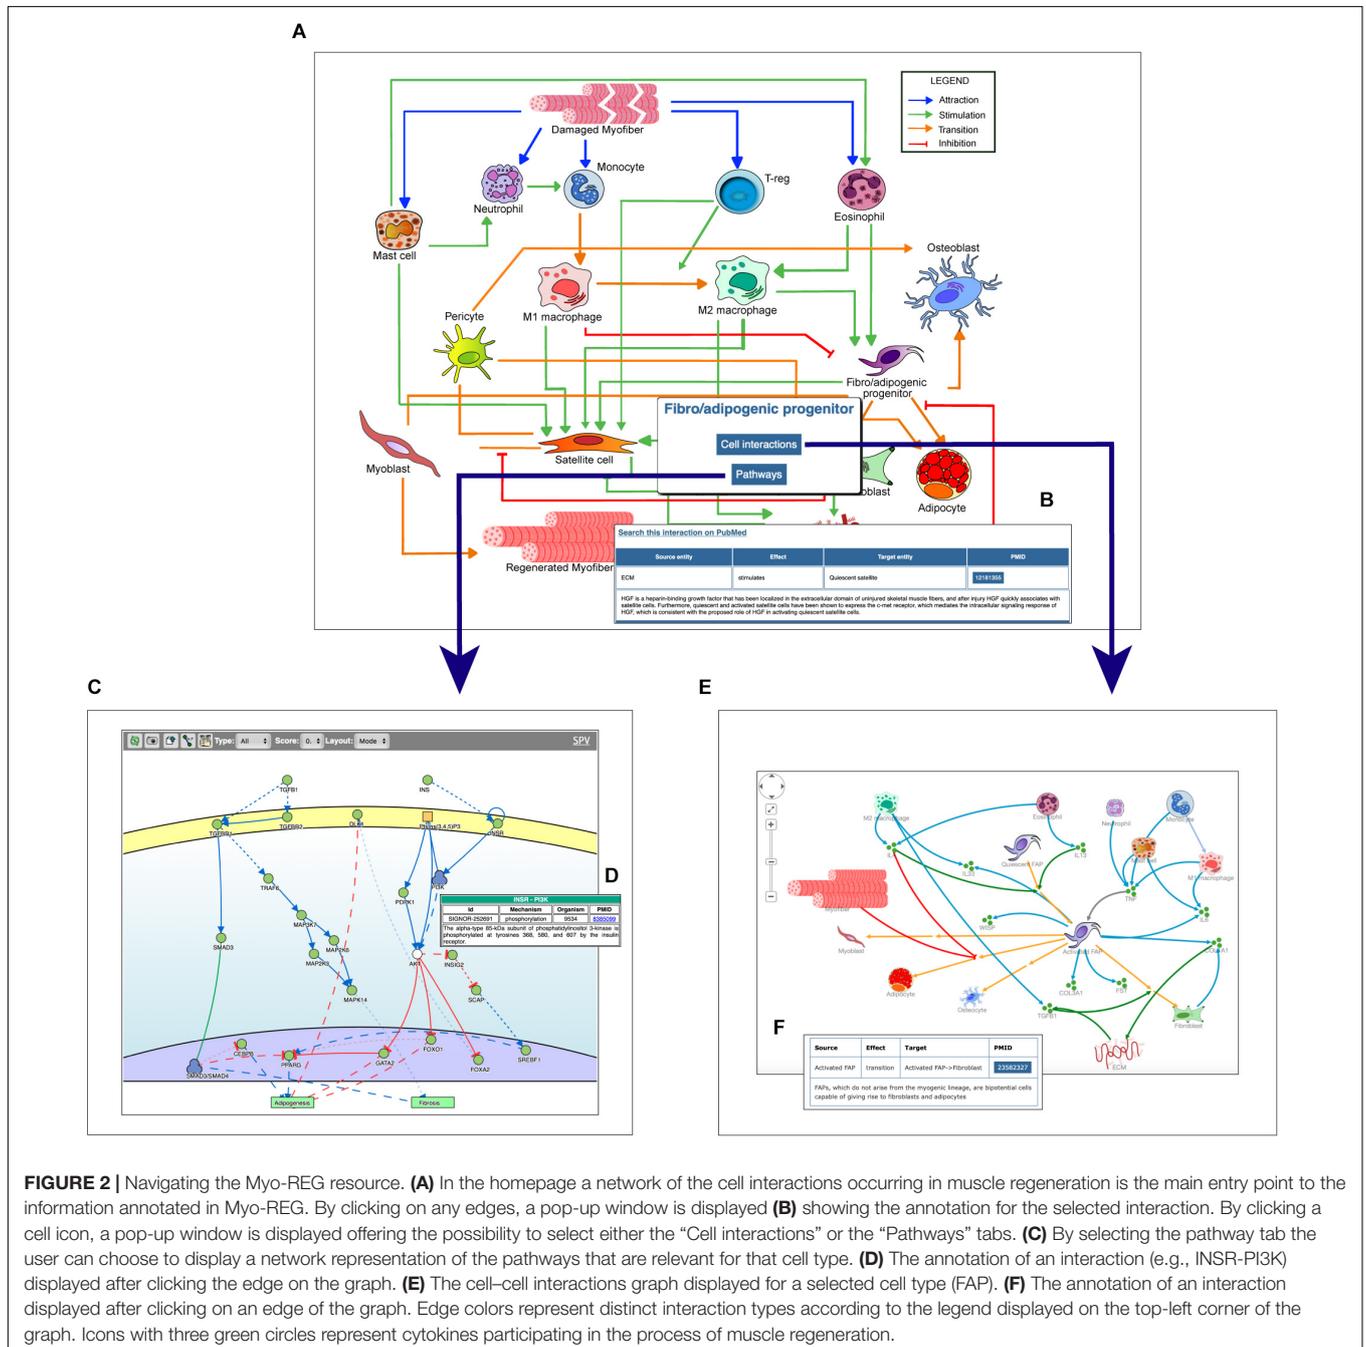

**FIGURE 1 |** Organization of the Myo-REG home page. Myo-REG allows users to explore several aspects of muscle regeneration. The data types that are annotated in the resource include cell and signaling interactions, cell biomarkers and gene expression data. Blue arrows denote (chemo-) attractions, green arrows denote stimulations, orange arrows are transitions (mostly differentiation processes) and red T-shaped arrows are inhibitions.

linked by edges that are directed (from modifiers to targets) and signed (activates/inactivates).

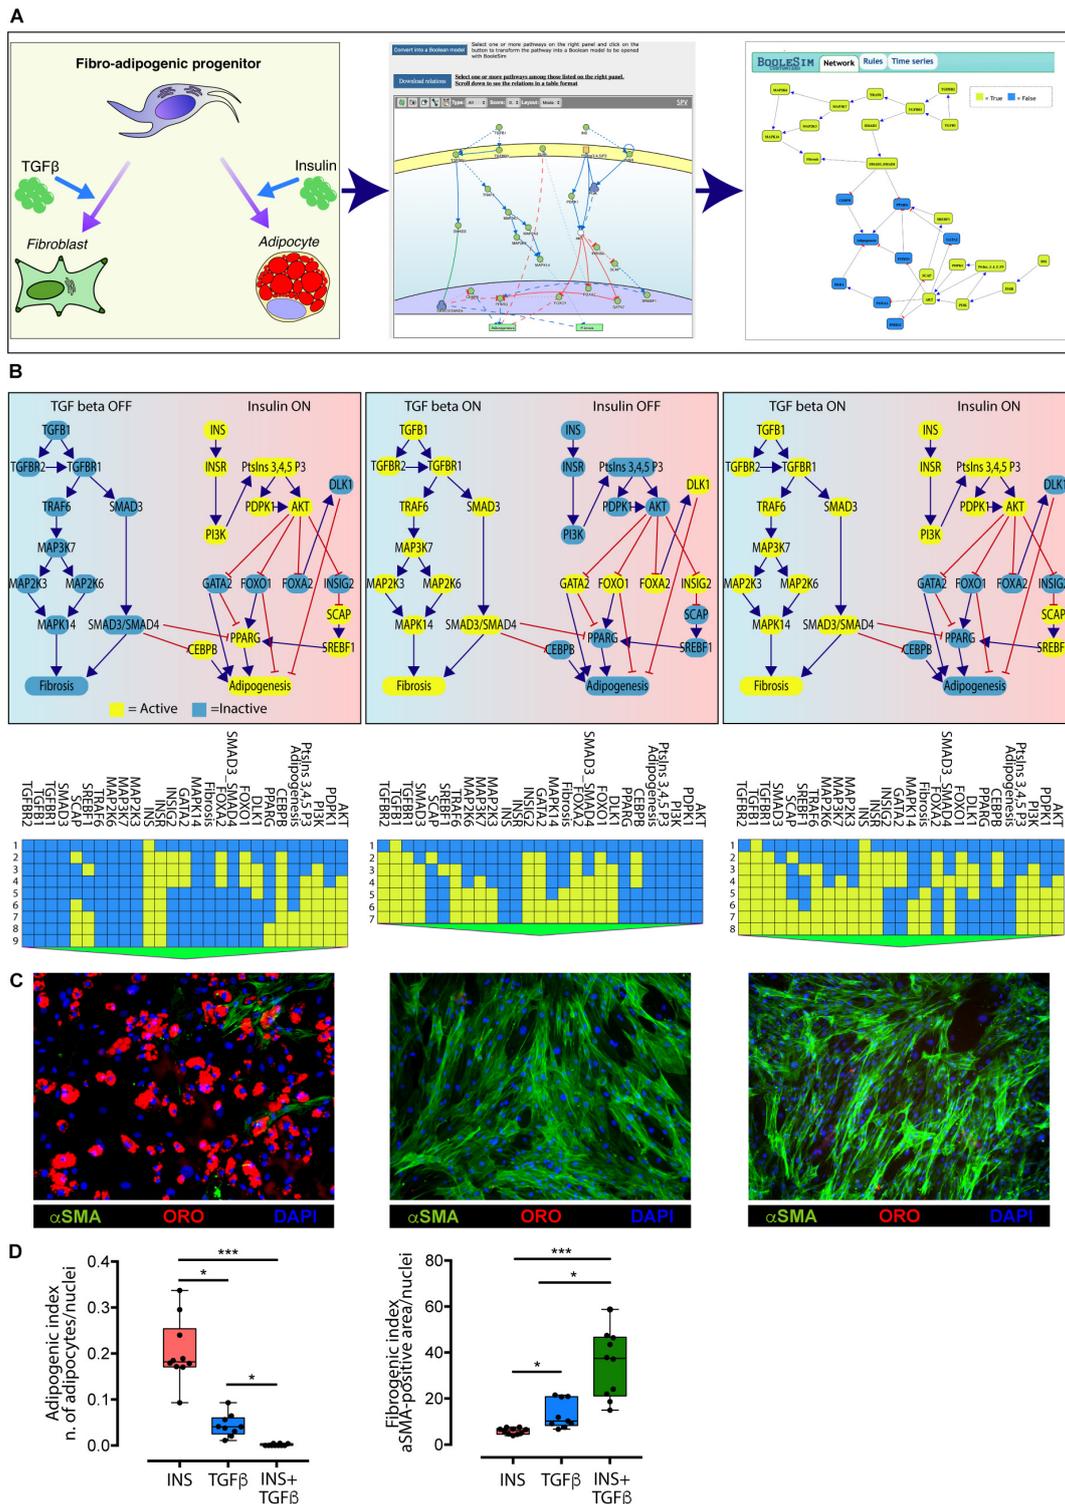

Finally, in Myo-REG causal interactions are organized into pathways. The cell interactions in the muscle, either by direct contact or via secretion of cytokines, impact on the activation of pathways in target cells, thus changing their phenotypes. Pathways are abstractions linking a subset of signaling molecules by a chain of causal relations. For each cell type in Myo-REG, we manually curated pathways defining a set of causal interactions that explain the cell response to molecular signals,

in the context of muscle regeneration. Pathways are shown as signed directed graphs that link an input signal to an output phenotype. The definition of the molecular entities that should be included in a pathway is subjective. Most pathways in Myo-REG include as few as 10–20 entities (mini-pathways) and initiate with an environmental signal to terminate with a phenotype. The compartmental representation of the pathway graphical display provides a user-friendly way to organize the signaling cascade in distinct cellular spaces: extracellular, plasma membrane, cytoplasm and nucleus. To date, Myo-REG stores a

**FIGURE 2 |** Navigating the Myo-REG resource. **(A)** In the homepage a network of the cell interactions occurring in muscle regeneration is the main entry point to the information annotated in Myo-REG. By clicking on any edges, a pop-up window is displayed **(B)** showing the annotation for the selected interaction. By clicking a cell icon, a pop-up window is displayed offering the possibility to select either the “Cell interactions” or the “Pathways” tabs. **(C)** By selecting the pathway tab the user can choose to display a network representation of the pathways that are relevant for that cell type. **(D)** The annotation of an interaction (e.g., INSR-PI3K) displayed after clicking the edge on the graph. **(E)** The cell-cell interactions graph displayed for a selected cell type (FAP). **(F)** The annotation of an interaction displayed after clicking on an edge of the graph. Edge colors represent distinct interaction types according to the legend displayed on the top-left corner of the graph. Icons with three green circles represent cytokines participating in the process of muscle regeneration.

(Continued)

**FIGURE 4 |** Conversion of the TGFβ and INS pathways into an executable Boolean network. **(A)** The ability of FAPs to differentiate into either adipocytes or fibroblasts (left panel) is represented in Myo-REG as a union of two selected pathways: INSR and TGFβ (middle panel). Pathways are automatically converted into a Boolean network and input into a customized BooleSim application (right panel). Panel **(B)** depicts the system stationary phase in conditions in which the FAPs are stimulated with insulin (left panel), TGF beta (middle panel) or both (right panel). The network evolution is represented as a heatmap below each simulation. Yellow means active (True) while blue is inactive (False). **(C)** Representative immunofluorescence (20x magnification) of FAPs from wild type mice stimulated to differentiate in the presence of insulin (left) ( $n = 10$ ), TGF beta (middle) ( $n = 9$ ) or both stimuli (right) ( $n = 10$ ). Adipocytes (red) and fibroblasts (green) were stained with oil Red O

**FIGURE 4 |** Continued

(ORO) and with an anti- $\alpha$ -SMA antibody, respectively. Nuclei (blue) were stained with Hoechst 33342. **(D)** Left chart: quantification of the percentage of green area with insulin treatment as reference group. Right chart: quantification of the number of adipocytes normalized over the number of nuclei per field (insulin treatment as reference group). The statistical significance was defined as: \* $p < 0.05$ , \*\* $p < 0.01$ , and \*\*\* $p < 0.001$ .

ID) in the search entity-form the tool returns a table that reports the protein matches in the database. Users can choose, via check boxes, to display either the signaling partners of the query protein or the Myo-REG mini-pathways the protein is involved in. Alternatively, if the query entity is a cell type, the result page displays a table allowing to choose whether to display a Cytoscape view of the cells interacting with the query cell or the signaling pathways that are associated to that cell in Myo-REG. A second search form allows to retrieve articles containing any keyword in connection with the term “muscle” in an article title or abstract. A programmatic query is sent to PubMed to retrieve articles whose content may be related to the query term in the context of muscle regeneration. The search results are reported as a table presenting the title, PMID, author list, publication title, publication year and journal name.

## The Navigation Toolbar

Additional data and tools can be accessed via the navigation toolbar (Figure 3).

From the tab “gene expression,” users are also allowed to navigate through the single-cell RNAseq gene expression page, showing the expression level of almost 15000 genes in mouse hind limb muscle. Single-cell RNAseq data have been retrieved from the *Tabula muris* project (Tabula Muris Consortium et al., 2018) and displayed as tSNE plots where the expression level of desired genes is reported in a color scale based on the RNA counts in the distinct cell populations.

Muscle resident cells are classified into different cell types according to the presence of antigens that are differently expressed in the different cell types. In Myo-REG these antigens are dubbed “Biomarkers.” Biomarkers can be accessed by clicking the “Biomarkers” tab in the navigation bar (Figure 3B). This action leads to a search form that allows to select the organism (*H. sapiens* or *M. musculus*), and from a drop-down menu, the cell type of interest. The search results are displayed in a table format where each biomarker is reported with its gene name and synonyms, the UniProt identifier, a list of additional cell types expressing that biomarker and reference to the literature supporting its expression in the selected cell type.

To assist the resource exploration, we have also compiled a user-guide (Figure 3D) describing in more detail and illustrating with self-explanatory screenshots the main operations that a Myo-REG user could consider. All the data annotated in Myo-REG can be downloaded from Myo-REG for local use via the “download” tab. Finally, the “statistics” tab gives access to a variety of analyses of the database content.

## Executable Boolean Models

To facilitate hypothesis generation, we implemented a script to convert logic into Boolean models for any pathway of interest

curated in Myo-REG. The models are then displayed via a customized BooleSim application (Bock et al., 2014). BooleSim is a simple network simulator, which allows to create, edit and simulate networks based on Boolean logic. The automatically generated models can be modified, for instance by editing Boolean rules, thereby allowing to introduce into the model additional information. The generated models can be used to perform *in silico* simulations under different conditions. To illustrate the potential of this tool we will assemble and analyze a model of FAP differentiation when stimulated by insulin and TGF $\beta$ .

Fibro/adipogenic progenitors are muscle resident interstitial cells of mesenchymal origin (Joe et al., 2010; Uezumi et al., 2010; Stumm et al., 2018). When activated, they transiently support satellite cells proliferation through the establishment of several paracrine signals (Joe et al., 2010; Murphy et al., 2011). In pathological conditions, such as in Duchenne muscular dystrophy, FAPs can differentiate into fibroblasts or adipocytes, contributing to the deposition of fat tissue and to the formation of scar infiltrations (Uezumi et al., 2011). When treated *ex vivo* with insulin (INS) FAPs differentiate into adipocytes (Joe et al., 2010; Reggio et al., 2019b), while the treatment with TGF $\beta$  triggers their fibrogenic differentiation (Uezumi et al., 2010).

Myo-REG stores curated pathways describing FAP response to INS and TGF $\beta$  and other stimuli (Marinkovic et al., 2019; Reggio et al., 2019a). In Figure 4, we have merged the two pathways and automatically converted the resulting causal network into an executable Boolean network.

The network encompasses 27 nodes linked by negative (inhibitions) or positive (activations) relationships. The nodes can have a value of either “True” or “False” (yellow and blue in Figure 4, respectively). During the simulation steps the value of each node is updated according to the values of the upstream nodes and to the rules defined in section “Materials and Methods.” Only two nodes (INS and TGF $\beta$ ) have no incoming edge and represent the input of the system, while “Adipogenesis” and “Fibrosis” are output nodes (nodes without outgoing edges) and are used as read-outs. In the simulation in Figure 4 all nodes have an initial value set to False, except for the input nodes that define the experimental conditions. The values of the readouts when the system is stabilized, however, only depend on the initial values of the input nodes, irrespective of the initial values of the remaining nodes.

As shown in the left panel of Figure 4B, when the value of the INS input node is set to “True” (yellow) and the TGF $\beta$  to “False” (blue) after a few simulation steps the system reaches a steady state where the adipogenesis node is True and fibrogenesis is False. Conversely when TGF $\beta$  is set to True and INS is False the model predicts that at steady state fibrogenesis is True (Figure 4B, middle panel). The times series data displayed below each panel

show the evolution of the system starting from the initial condition. This model prediction is coherent with experimental observations. Interestingly, the model predicts that, when FAPs are given both the INS and TGF $\beta$  stimuli, the antiadipogenic TGF $\beta$  signal wins over the pro-adipogenic insulin signal and drives the system into fibrogenesis (Figure 4B, right panel). Also this prediction was verified experimentally (Figures 4C,D).

To verify the predictions of our model, FAPs from *mdx* mice were grown and differentiated in different culture setups. Specifically, cells were differentiated into adipocytes by incubating cells with a pro-adipogenic medium, while fibrogenic differentiation was performed by incubating FAPs with TGF $\beta$  (5 ng/ml). Co-treatment was performed with the same experimental modalities.

Consistently with the model prediction in the presence of insulin, FAPs undergo adipogenesis, and the majority of cells differentiated into mature adipocytes as detected by Oil Red O staining (Figure 4D). By contrast, stimulation with TGF $\beta$  promoted fibroblastic differentiation as monitored by  $\alpha$  Smooth Muscle Actin ( $\alpha$ SMA) staining. Importantly, the co-treatment with both insulin and TGF $\beta$  induced FAPs to differentiate into fibroblasts, as predicted by the model. These results confirm the predictive power of the *in silico* model derived from Myo-REG.

## DISCUSSION

Myo-REG is a web portal designed to facilitate access to organized information in the context of muscle regeneration. The user-friendly interface and the variety of annotated experimental information are intended to help myologists to integrate the different data-types that are relevant for their work.

Myo-REG is a multi-scale, manually annotated, resource that is one in a kind, since it provides information on how intracellular molecular events affect cell phenotypes and cell-communication during muscle regeneration.

Although we aimed at high coverage and accuracy, we are aware that our effort is likely to have missed some relevant piece of information while some relationships might have been annotated incorrectly. We are committed to continue curating this resource to improve accuracy and coverage by including new data, as published. This can better be achieved if colleague myologists, that find this resource useful, interact with us and send feedback and suggestions for improvements and

## AVAILABILITY OF DATA AND MATERIALS

Project home page: <https://myoreg.uniroma2.it>.

Operating system(s): Platform independent.

Programming language: Html5 for the website backbone, Css3 for styles, Php5, R and JavaScript for the scripting part.

Other requirements: Optimized for Mozilla Firefox and Safari browsers.

The data used and/or analyzed during the current study are available from the corresponding author on reasonable request.

## AUTHOR CONTRIBUTIONS

AP, LC, and GC conceptualized the project, and curated cell-cell interactions, pathways, and biomarkers. LLP and CF curated pathways and biomarkers. AC, FF, CG, GG, MI, LL, AR, MR, FS, SV, SP, LP, and AZ curated pathways. AP developed the database, web site, and scripting, performed the cell culture, treatments, immunofluorescences, image acquisition, and statistical analyses, and wrote the original draft. EM implemented the Boolean network transformation script. AP, AR, MR, and GC conceptualized the wet lab experiments. AP, CG, LC, and GC wrote and edited the manuscript. AP and GC prepared the figures. All authors contributed to data curation and read and approved the final manuscript.

## FUNDING

This work was supported by a grant of the European Research Council (Grant No. 322749) and by AIRC (14135) to GC.
