Pulmonary hypertension (PH) is a critical and dangerous disease in cardiovascular system. Pulmonary vascular remodeling is an important pathophysiological mechanism for the development of pulmonary arterial hypertension. Pulmonary artery smooth muscle cell (PASMC) proliferation, hypertrophy, and enhancing secretory activity are the main causes of pulmonary vascular remodeling. Previous studies have proven that various active substances and inflammatory factors, such as interleukin 6 (IL-6), IL-8, chemotactic factor for monocyte 1, etc., are involved in pulmonary vascular remodeling in PH. However, the underlying mechanisms of these active substances to promote the PASMC proliferation remain to be elucidated. In our study, we demonstrated that PASMC senescence, as a physiopathologic mechanism, played an essential role in hypoxia-induced PASMC proliferation. In the progression of PH, senescence PASMCs could contribute to PASMC proliferation via increasing the expression of paracrine IL-6 (senescence-associated secretory phenotype). In addition, we found that activated mTOR/S6K1 pathway can promote PASMC senescence and elevate hypoxia-induced PASMC proliferation. Further study revealed that the activation of mTOR/S6K1 pathway was responsible for senescence PASMCs inducing PASMC proliferation via paracrine IL-6. Targeted inhibition of PASMC senescence could effectively suppress PASMC proliferation and relieve pulmonary vascular remodeling in PH, indicating a potential for the exploration of novel anti-PH strategies.

Keywords: pulmonary artery smooth muscle cells senescence, interleukin-6 (IL-6), mTOR- S6K1 signaling, pulmonary hypertension, proliferation

INTRODUCTION

Pulmonary hypertension (PH) is a malignant disease of cardiovascular system caused by pulmonary arteriole vascular hyperplasia, which leads to the progressive increase of pulmonary vascular resistance and the increase of right ventricular load and finally leads to right heart failure (Lan et al., 2018). Pulmonary vascular remodeling is the key pathophysiological mechanism of the occurrence and development of PH (Shah, 2012; Maron et al., 2020). Pulmonary vascular remodeling involves a variety of cells, including vascular endothelial cells, pulmonary artery smooth muscle cells (PASMCs), and multiple inflammatory cells. However, proliferation, hypertrophy, and increased secretory activity of PASMCs are the main pathological changes of pulmonary vascular remodeling in PH. In recent years, new drugs for the treatment of PH have been found for different targets, such as soluble ornithine cyclase agonists, tyrosine kinase inhibitors, and so on. Although these drugs have a certain effect on improving the clinical symptoms of patients with PH, they still cannot effectively reduce the mortality (Macchia et al., 2014; Samokhin et al., 2020). The reason is that the pathogenesis of the disease has not been fully clarified (Tang et al., 2016; Frid et al., 2020). Therefore, in-depth study of the pathogenesis of pulmonary vascular remodeling in PH is of great significance for finding and confirming targets and developing new drugs for the treatment of PH.

Cell senescence is a process characterized by irreversible loss of cell growth and proliferation, which is mainly characterized by the cessation of cell replication, cell cycle arrest in G₀/G₁ phase, telomere shortening, up-regulation of senescence-related genes, and significant increase of specific P-galactose activity (Leon and Gustafsson, 2016; van der Feen et al., 2019). It is reported that cell senescence is closely related to the occurrence and development of many human diseases (Wang et al., 2015; Leon and Gustafsson, 2016). Previous studies have shown that senescent cells eventually lead to programmed death apoptosis (Hoenicke and Zender, 2012). Recent studies have found that senescent cells can show “senescence but not aging”; senescent cells can promote the occurrence and development of disease by secreting cytokine senescence-associated secretory phenotype (SASP). For example, SASP secreted by aging fibroblasts can promote the epithelial-mesenchymal transition of epithelial cancer cells (Coppe et al., 2010) and improve its tumorigenic potential (Krtolica et al., 2001). However, the role of vascular smooth muscle cells senescence in the proliferation of PASMCs in PH remains unclear.

It has been found that endothelial cell senescence is involved in the formation and development of atherosclerosis, diabetes, vascular remodeling and inflammation, blood test blockage, and so on (Wang and Bennett, 2012; Kim et al., 2020). In recent years, studies have proved that the senescence and phenotypic changes of vascular smooth muscle cells also play an important role in the occurrence and development of cardiovascular diseases (Song et al.,

2012; Gardner et al., 2015). For example, vascular smooth muscle cells senescence can promote atherosclerosis and plaque vulnerability (Rabinovitch, 2012); senescence can also up-regulate the secretion of interleukin 6 (IL-6) and CCL2 production in aortic smooth muscle cells, causing chronic inflammation and promoting atherosclerosis (Song et al., 2012). It is worth noting that recent studies have found that PASMC senescence is significantly increased in (pulmonary vascular remodeling in chronic obstructive pulmonary disease (COPD) (Noureddine et al., 2011). In our pre-experiment, we found that after hypoxia treatment, the number of β -galactosidase-positive cells in PASMCs increased significantly, and the expression of senescence index p21 was significantly up-regulated. Therefore, we speculate that PASMC senescence may play an important role in hypoxia-induced PASMC proliferation and PH.

As mentioned previously, PASMC senescence plays an important role in hypoxia-induced pulmonary vascular remodeling, so what is the mechanism by which aging PASMCs promote PASMC cell proliferation and pulmonary vascular remodeling? It has been reported that senescent cells can produce a variety of cytokines (SASP), including IL-6, IL-8, tumor necrosis factor α (TNF- α), monocyte chemoattractant protein 1 (MCP-1), etc. (Coppe et al., 2010; Acosta et al., 2013), which promotes the occurrence and development of tumor; paracrine IL-6 can induce the proliferation of human lung fibroblasts and the growth and metastasis of pancreatic cancer cells (Huang et al., 2016; Klee et al., 2016). In addition, Gardner and colleagues have shown that aging aortic smooth muscle cells promote the occurrence and development of atherosclerosis by secreting SASP (IL-1 α) (Gardner et al., 2015). These results suggest that senescent smooth muscle cells can secrete SASP and play an important role in the process of cardiovascular disease. Studies have confirmed that neutralizing antibodies against IL-6 can inhibit the proliferation of HepG2 cells (Hu et al., 2017). In addition, it was found that miR-195 could reduce the levels of IL-1 β , IL-6, and IL-8 and then inhibit the proliferation, migration, and intimal hyperplasia of vascular smooth muscle cells (Wang et al., 2012). More importantly, senescence PASMCs in COPD promote PASMC proliferation and pulmonary vascular remodeling by paracrine IL-6 (Noureddine et al., 2011). PASMCs senescence is markedly an increase in hypoxia-induced PH and senescence PASMCs can promote the proliferation of PASMCs by secreting SASP. And the senescence of PASMCs is mainly secreting SASP in which cytokines are involved in regulating the proliferation of PASMCs. In order to confirm which cytokines are mainly involved in the proliferation of PASMCs, we examined the expression of IL-1 β , transforming growth factor β (TGF- β), IL-6, IL-8, MCP-1, and TNF- α in the culture medium of PASMC senescence induced by hypoxia. The results of pre-experiment showed that the expression of IL-6 in hypoxia-induced PASMC senescence was significantly increased. The results suggest that IL-6 may play a more important role than other cytokines. Therefore, we speculate that hypoxia can induce the senescence of PASMCs, and senescence of PASMCs may promote the abnormal proliferation of PASMCs by paracrine IL-6.

MATERIALS AND METHODS

Animals

Male Sprague–Dawley (SD) rats (weighing 180–220 g) were obtained from the Laboratory Animal Center, University of South China (Hengyang, China). All surviving animals were handled in accordance with the National Institutes of Health Guide for the Care and Use of Laboratory Animals. The experimental protocol was approved by the medicine animal welfare committee of University of South China (Hengyang, China).

Separation, Culture, and Identification of PSMCs in Rats

The primary PSMCs in SD rats are cultured by tissue walling method; 110–150 g male SD rat was anesthetized by intraperitoneal injection of 10% chloral hydrate (3 mL kg⁻¹). The pulmonary artery was quickly taken out from the SD rat; the outer membrane of blood vessel was gently removed; the intima was removed with ophthalmic forceps after longitudinal cutting, cut into 1 × 1-mm³ fragments, and was seeded in 25-cm² flasks; the growth of cells was observed by inverted microscope after 4 to 5 days of culture in a complete incubator [20% fetal bovine serum (FBS)–Dulbecco modified Eagle medium (DMEM)] and 1% antibiotic (penicillin–streptomycin). The tissue block was carefully removed with dental probe when the cells around the tissue block were almost full (about 6 days), and culture was continued for 1–3 days, at 37°C under 5% CO₂ in DMEM containing 20% FBS. The primary PSMCs were observed under inverted microscope. The cells grew in a long spindle shape with abundant cytoplasm; when they grew compactly, they were arranged in parallel bundles and distributed in a characteristic “peak valley” shape of smooth muscle cells. The cells were then counted and seeded (passage 2) in 75-cm² flasks. Purified PSMCs were screened by 0.25% pancreatic enzyme digestion and gradient digestion. The third-generation cells were identified by immunohistochemistry staining using an antibody against smooth muscle α -actin (ab7817, 1:50; Abcam, Hong Kong, China). The purity of the PSMCs can reach more than 96%. PSMCs between passage 3 to 10 were used for the next experiments.

Establishing of Hypoxia-Induced PSMC Proliferation

All experimental animal procedures were conducted in accordance with human animal care standards with approval from the University of South China Ethics Committee (Hengyang, China). The animals were acclimated to the environment for 1 week prior to treatment under specific pathogen-free conditions. The PSMCs were cultured with DMEM medium of 10% FBS and treated with DMEM medium of 1% FBS for 24 h when the cells cultured to confluence for 75%. In the following experiment, the normoxic group was cultured in incubator of 37°C, 5% CO₂. The hypoxia group (3% O₂) was placed in a small hypoxia chamber. Hypoxia significantly induced PSMC proliferation by CCK8 kit, and 48-h proliferation range reached the maximum; therefore, the 48 h was selected as the

optimized time point for subsequent experiments. The small hypoxia chamber (Changjin, China) consists of 92% N₂, 5% CO₂, and 3% O₂.

Detection of PSMC Senescence by β -Galactosidase Staining Kit

The cell senescence β -galactosidase staining kit (Beyotime Biotechnology, Shanghai, China) was used to detect the level of senescence-associated β -galactosidase activity in hypoxia-induced PSMC proliferation. SA- β -Gal staining was performed according to the manufacturer's instructions. Under an optical microscope, it can be observed that senescence cells are dyed into blue in hypoxia-induced PSMC proliferation. Briefly, cells were placed in a 3% small hypoxia compartment for 48 h. Next, cells were washed twice in phosphate-buffered saline (PBS); staining solution was added to the PSMCs for 15 min at room temperature. Then cells were washed with PBS for three times and stained with working solution overnight at a 37°C electrothermal incubator.

Western Blot

For protein extraction, isolated PSMCs were washed with PBS and lysed with RIPA lysis buffer. RIPA lysis buffer and phenylmethylsulphonyl fluoride (9:1) were used to extract protein. Protein contents were measured by BCA protein assay kit. In addition, separation of proteins by size was performed using sodium dodecyl sulfate–polyacrylamide gel by electrophoresis. After electrophoresis, proteins from the gel were transferred onto polyvinylidene difluoride (Billerica, MA, United States) membranes (Millipore). After transfer, the objective proteins membranes were saturated with 5% milk for 2 h. The objective proteins membrane then incubated overnight at 4°C with specific primary antibodies: p21 (1:2,000 dilution) and PCNA (1:2,000 dilution) were purchased from Abcam (Cambridge, United Kingdom); PI3K rabbit antibody (1:1,000 dilution) and m-TOR (1:1,000 dilution) rabbit monoclonal antibody were obtained from Cell Signaling Technology (Danvers, MA, United States); GAPDH (1:5,000 dilution) and β -actin (1:5,000 dilution) mouse antibody were from Proteintech (Shanghai, China). Horseradish peroxidase–conjugated anti-rabbit or anti-mouse immunoglobulin G was used to amplify the signals from the primary antibody. The densitometry analysis of objective protein bands was performed using software (AlphaMager TM 2200). Protein expression was reported as the protein/ β -actin ratio and expressed as arbitrary units.

PSMC Proliferation Detection by CCK-8

Pulmonary artery smooth muscle cell proliferation was measured by Cell Counting Kit-8 (CCK-8) assay (Beyotime, C0038, China) according to the manufacturer's instructions. Cell Counting Kit-8 (CCK-8) is a water-soluble tetrazolium salt, which is reduced to orange-yellow xanthium by some dehydrogenase in mitochondria in the presence of 1-Methoxyphenazine methosulfate. The darker the cell color, the more the number of methylinders produced, and the more the number of living cells. The number of living cells can be indirectly reflected by the light

absorption value measured at 450-nm wavelength by enzyme-labeled instrument. Briefly, the cells were seeded onto 96-well dishes. The normoxic group cells were seeded in incubator of 37°C, 5% CO₂; the hypoxia group (3% O₂) cells were cultured in a small hypoxia chamber for 48 h in 10% fetal bovine serum (Grand Island, NY, United States) before 6 h in 0.1% FBS. After 48 h, the medium was changed to the same medium supplemented with the CCK8 liquid according to 10% of the total volume of each well medium, and then the cells were incubated for 1–2 h, and the absorbance was detected at the wave length of 450 nm using an enzyme labeling instrument.

Measurements of IL-6 by Enzyme-Linked Immunosorbent Assay

Soluble factors were measured in cell medium. The main principle of IL-6 enzyme linked immunosorbent assay (ELISA) Kit (BOSTER, EK0412) is that the substrate TMB is catalyzed by peroxidase to blue, which changes from blue to yellow under the action of acid. The level of IL-6 in the sample is positively correlated with the depth of color. For cell medium determinations, PSMCs from early and late passages were grown to confluence in DMEM containing 20% fetal calf serum. The medium was then removed, and the cells subjected to growth arrest. After 48 h of incubation, the conditional medium was used for quantitation of IL-6 using Quantikine ELISA kits according to the manufacturer's instructions. The OD value was measured at 450 nm in the microplate reader.

RNA Concentration Determination and Quality Evaluation

The RNA concentration was determined by biological spectrophotometer, the sample type was selected RNA, the determination system was 2 μL RNA sample solution, and the blank correction was carried out with 2 μL DEPC water before determination. OD260/230, OD260/280, RNA concentration, and A320 were recorded to evaluate RNA quality (the optimum range of A260/A280 is 1.8–2.0; less than 1.8 indicates that the contamination of protein or other organic matter in the solution is obvious; more than 2.2 indicates that the RNA may be degraded; the A320 value represents the number of salt ions in the RNA, and the general value less than 0.01 indicates that the saline ions content is very small).

mRNA Reverse Transcription

Total RNA was extracted from cultured cells using Trizol reagent (Invitrogen, Carlsbad, CA, United States). For detection of mRNA expression, RNA (0.2–0.5 μg) was subjected to reverse transcription reaction using the PrimeScript reverse transcription reagent Kit (DRR037A; TaKaRa, Dalian, China) according to Takara Company's reverse transcription kit. The RNA reverse transcription was carried out by the one-step method.

Real-Time Polymerase Chain Reaction

Quantitative analysis of mRNA expression was performed using SYBR Premix Ex Taq (DRR420A; TaKaRa) at ABI 7300 system (7300 Real-time PCR instrument, ABI Company). The

target gene fragment was amplified by PCR reaction on the fluorescence real-time quantitative polymerase chain reaction (qPCR) instrument. PCR cycling conditions were as follows: an initial incubation at 95°C for 15 s, followed by 40 cycles of denaturation at 95°C for 5 s, and annealing at 60°C for 31 s.

Rapamycin of mTOR Inhibitor-Treated PSMCs

After taking the logarithmic growth stage cell seed plate, the fusion rate reached 70–80%, the low serum was synchronized for 24 h, and then the target cells were treated with different concentrations of rapamycin: normoxic group (normoxia): cell normal oxygen partial pressure (21% O₂) treatment; hypoxia model group (hypoxia): cells were treated with 3% O₂; hypoxia + 20 nM rapamycin group: the cells were added 20 nM rapamycin and cultured in hypoxia incubator for 48 h; hypoxia + 40 nM rapamycin group: the cells were added 40 nM rapamycin and cultured in hypoxia incubator for 48 h; and hypoxia + 80 nM rapamycin group: the cells were added 80 nM rapamycin and cultured in hypoxia incubator for 48 h. After the treatment, the expression of related proteins was collected according to the impassable experimental purpose.

Small Interference RNA Transfection

The mTOR siRNA was purchased from RiboBio (Guangzhou, China). TurboFect transfection reagent (#0531; Thermo Scientific, United States) was used for cell transfection. The mTOR siRNA interference was transiently transfected. When PSMC growth reaches 60–70% fusion, the low serum medium was used for synchronization for 24 h. According to the experimental groups, a certain volume of serum-free culture medium and unrelated fragment transfection complex was added into the cells at 37°C, 5% CO₂ for 4–6 h and then was replaced by 20% fetal bovine serum and cultured for 48 h. The experiment was divided into six groups: normoxia group (normoxia): normal oxygen partial pressure (21% O₂) treatment; hypoxia group (hypoxia): cells were treated with 3% O₂; hypoxia + negative group: the cells were transfected with negative control (50 nM) for 4–6 h and then subjected to hypoxia for 48 h; hypoxia + siRNA (25 nM) group: the cells were transfected with siRNA (25 nM) for 4–6 h and then subjected to hypoxia for 48 h; hypoxia + siRNA (50 nM) group: the cells were transfected with siRNA (50 nM) for 4–6 h and then subjected to hypoxia for 48 h; and hypoxia + siRNA (100 nM) group: the cells were transfected with siRNA (100 nM) for 4–6 h and then subjected to hypoxia for 48 h. Transfection efficiency was evaluated by mTOR mRNA and protein expression using real-time PCR and Western blot analysis, respectively. Each experiment was repeated using primarily cultured cells (3–10 passages). The experiments were repeated three times.

Statistical Analysis

Statistical tests and graphs were done with SPSS 20.0 and GraphPad Prism 6.0. Values are expressed as fold change or mean ± standard error of the mean. Unpaired Student *t* tests

were used for comparisons between two groups, and one-way analysis of variance was used for multiple groups (SPSS 20.0, Chicago, IL, United States). $P < 0.05$ was considered statistically significant.

RESULTS

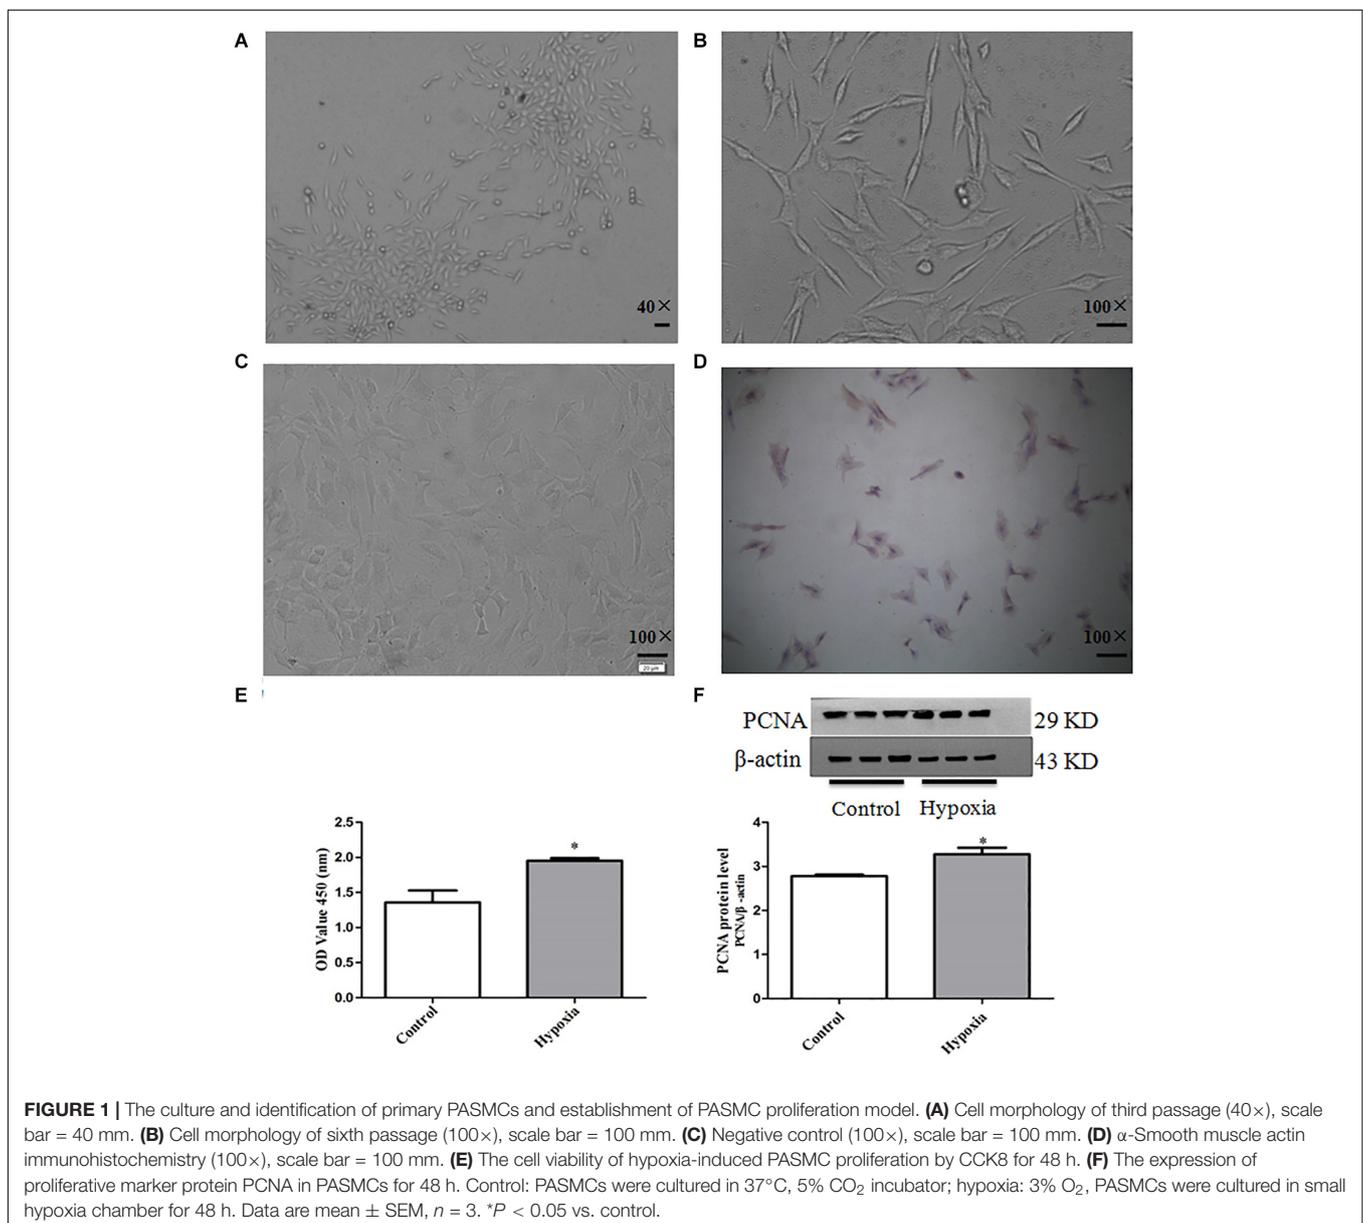

Increased PASC Senescence Occurred in Hypoxia-Induced PASC Proliferation

It can be observed that the primary PASCs show adherent growth; the cell morphology is mostly fusiform and abundant cytoplasm, which is the characteristic “peak valley” distribution using inverted phase contrast microscope after culturing for 5–7 days. **Figures 1A,B** show passages 3 and 6 PASCs,

respectively. α -Smooth muscle actin immunohistochemical showed that the positive stained rate of PASCs was more than 96%, and the purity was greater than 96% (**Figures 1C,D**).

The protein expression of PCNA was detected by Western blot, and the proliferation of PASCs was detected by CCK8 assay. The result of CCK8 showed that the proliferation of PASCs in hypoxia treatment group was higher than that of normoxic group ($P < 0.05$). The results of Western blot showed that the protein expression PCNA in hypoxia treatment group was significantly up-regulated compared with that in the normoxic group ($P < 0.05$) (**Figures 1E,F**). These results show that hypoxia can significantly promote PASC proliferation.

In order to confirm whether PASCs were senescent in hypoxia-induced PASC proliferation, we performed SA- β -Gal staining in hypoxia-induced PASC proliferation. We founded

that positive staining of SA- β -Gal was markedly increased in hypoxia-induced PASM proliferation (Figures 2A,B). These results suggest that PASM senescence is markedly increased in hypoxia-treated PASCs.

Further testing the expression of senescence markers p21 and p16 in hypoxia-induced PASM proliferation, we found that p21 and p16 were elevated in hypoxia-treated PASCs, indicating that they were senescent PASCs (Figures 2C,D). These results demonstrated PASM senescence may be tightly correlated with PASM proliferation in Hypoxia-induced pulmonary hypertension (HPH).

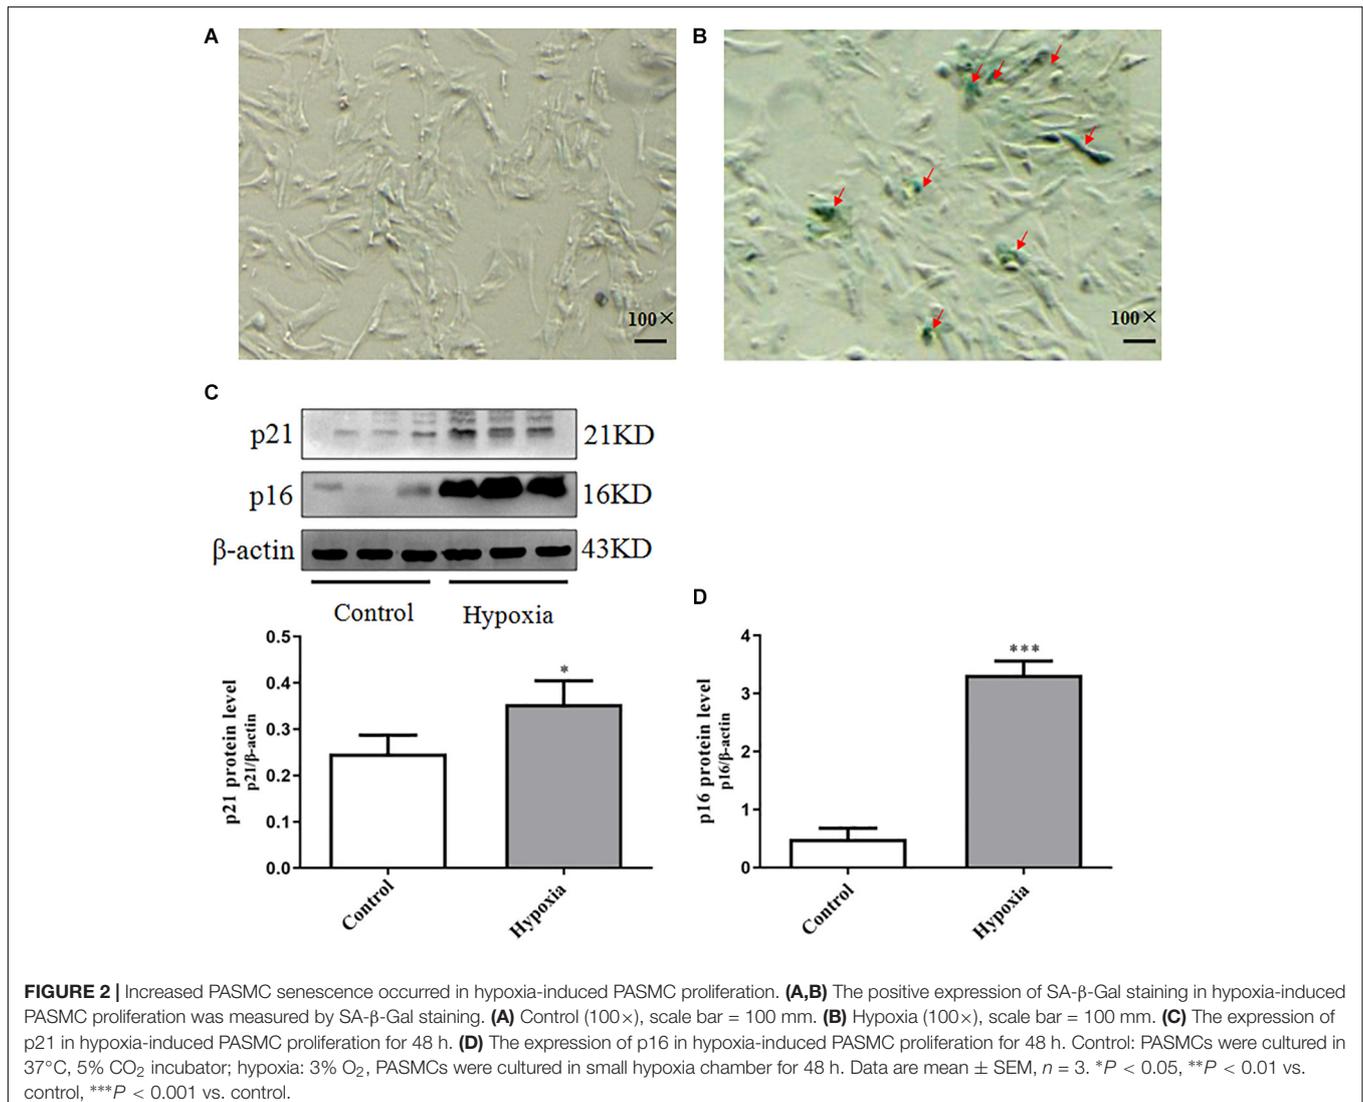

Senescent PASCs Promote PASM Proliferation by Paracrine IL-6

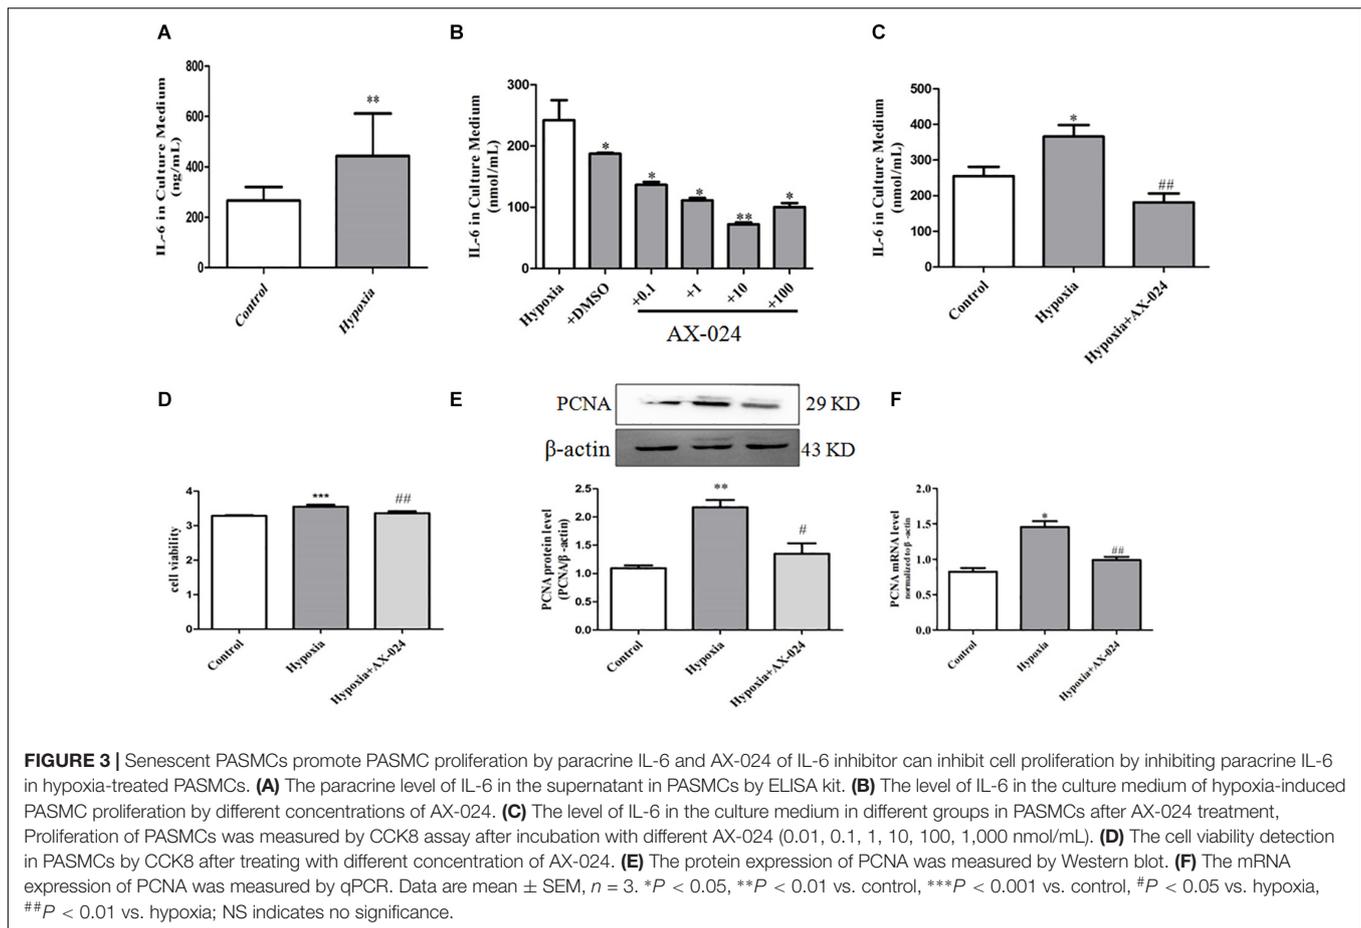

In order to further confirm the role of PASM senescence in hypoxia-induced PASM proliferation, we analyzed the level of IL-6 in the culture supernatant by ELISA. We found that the level of IL-6 in cell supernatant in hypoxia group was

significantly higher than that of normoxic group ($P < 0.01$). The results suggest that PASM senescence significantly increased in hypoxia-induced PASM proliferation; it was accompanied by up-regulation of IL-6 level in the culture supernatant, indicating that the senescence of PASCs can promote cytokine IL-6 paracrine (Figure 3A and Table 1).

IL-6 Inhibitor, AX-024 Can Inhibit Cell Proliferation by Inhibiting Paracrine IL-6 in Hypoxia-Treated PASCs

To further verify that PASM senescence promoted PASM proliferation by paracrine IL-6, AX-024 of IL-6 inhibitor was utilized. We found that the AX-024 with different concentration has different degree of inhibition against IL-6, and the inhibitor has the best inhibitory effect when the concentration of inhibitor was 10 nmol/mL (Figure 3B). The above result suggests that AX-024 of IL-6 inhibitors can significantly inhibit the paracrine of IL-6.

Then, the experiment was divided into normoxic group, hypoxia, and hypoxia + AX-024 group. ELISA was used to detect the paracrine level of IL-6 in the supernatant after AX-024 treatment. We found that the level of IL-6 in supernatant in the hypoxia + AX-024 group was significantly downregulated compared with that of the hypoxia group ($P < 0.001$) (Figure 3C and Table 2). The above results suggest that AX-024 of IL-6 inhibitor can inhibit the paracrine IL-6 in hypoxia-treated PSMCs.

To clarify the proliferation inhibition after AX-024 treatment of IL-6 inhibitor, CCK8 was utilized to detect the proliferation of PSMCs. Western blot and qPCR were used to detect the expression of protein and mRNA of proliferation marker protein PCNA. We found that AX-024 of IL-6 inhibitor

can significantly inhibit hypoxia-induced PSMC proliferation ($P < 0.05$) (Figure 3D). Western blot results showed that the protein expression of PCNA in hypoxia + AX-024 group was significantly lower than that in hypoxia group ($P < 0.05$) (Figure 3E). qPCR results showed that the mRNA expression of PCNA in hypoxia + AX-024 group was significantly inhibited compared with that of the hypoxia group ($P < 0.05$) (Figure 3F). The results indicated that AX-024 of IL-6 inhibitor can inhibit cell proliferation by inhibiting paracrine IL-6 in hypoxia-treated PSMCs.

Rapamycin Can Inhibit PSMC Senescence by Inhibiting the Activation of mTOR/S6K1 Signaling in Hypoxia-Treated PSMCs

In order to clarify the upstream regulation mechanism of PSMC senescence in hypoxia-treated PSMCs, rapamycin of mTOR inhibitor was utilized. We found that PSMCs cultured under hypoxia condition demonstrated a significant increase in phosphorylation of mTOR and S6K1 expression (Figures 4A,B). These data indicated that hypoxia can significantly induce mTOR and S6K1 activation in primarily cultured PSMCs, which may contribute to PSMC senescence, indicating that mTOR/S6K1

pathway was involved in PSMC senescence in hypoxia-induced PSMC proliferation.

To further confirm the key effect of mTOR/S6K1 pathway in hypoxia-induced PSMC proliferation, we used rapamycin of mTOR inhibitor in hypoxia-induced PSMC proliferation. We found that rapamycin, an inhibitor of mTOR, can strongly inhibit the activation of p-mTOR and p-S6K1 (Figures 4A,B). Importantly, we found that rapamycin could obviously suppress the expression of senescence-related protein P16 (Figure 4C), suggesting that mTOR promotes PSMC senescence in hypoxia-induced PSMC proliferation. Therefore, the above results indicate that rapamycin, an inhibitor of mTOR, could inhibit PSMC senescence in hypoxia-treated PSMCs.

Rapamycin Can Inhibit Hypoxia-Induced PSMC Proliferation

In order to further explore the regulation effect of mTOR on PSMC senescence, rapamycin was used to incubate PSMCs for 48 h, and then PSMC proliferation was analyzed by CCK8. We found that rapamycin could largely decrease the proliferation of PSMCs compared to that of the hypoxia group (Figure 5A) and also inhibit the mRNA expression of proliferation marker PCNA (Figure 5B), suggesting rapamycin, an inhibitor of mTOR, can suppress hypoxia-induced PSMC proliferation by inhibiting PSMC senescence.

mTOR siRNA Can Inhibit PSMC Senescence by Inhibiting the Activation of mTOR/S6K1 Signaling in Hypoxia-Treated PSMCs

To further confirm the key effect of mTOR/S6K1 pathway in hypoxia-induced PSMC proliferation, we used mTOR siRNA in hypoxia-induced PSMC proliferation. We found that mTOR siRNA can strongly inhibit the protein expression of mTOR and S6K1 (Figures 6A,B). Importantly, we found that mTOR siRNA could obviously suppress the expression of senescence-related protein P16 (Figure 6C), suggesting that mTOR promotes PSMC senescence in hypoxia-induced PSMC proliferation. The above results further support that mTOR could inhibit PSMC proliferation via inhibiting PSMC senescence.

mTOR siRNA Can Inhibit Hypoxia-Induced PSMC Proliferation

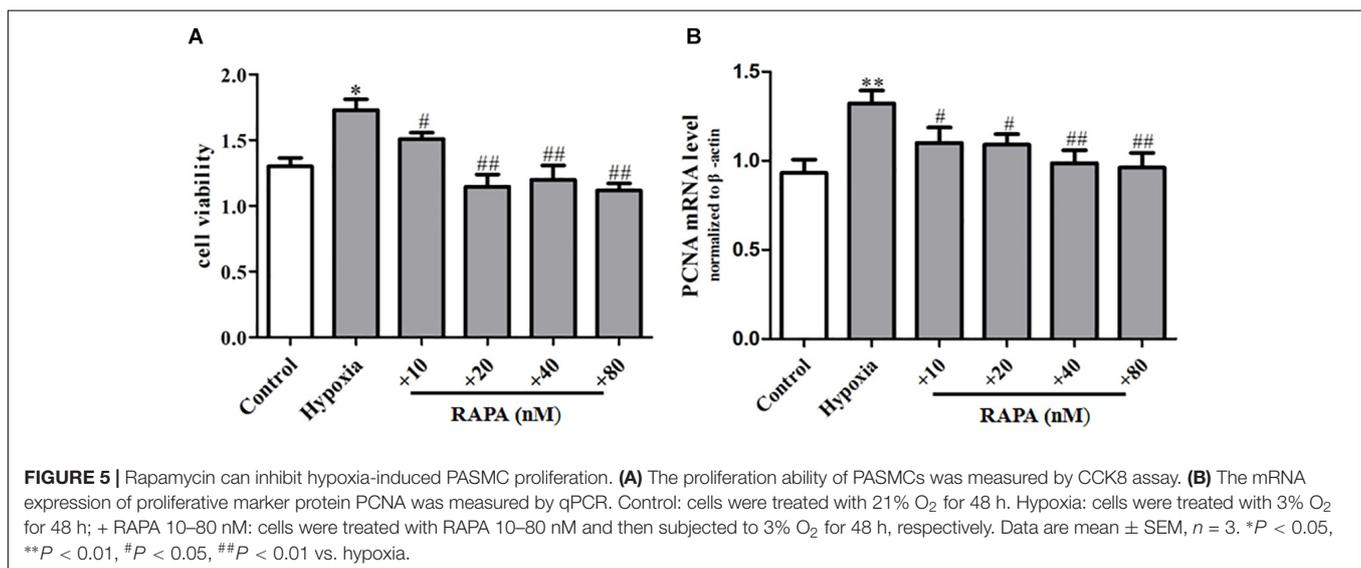

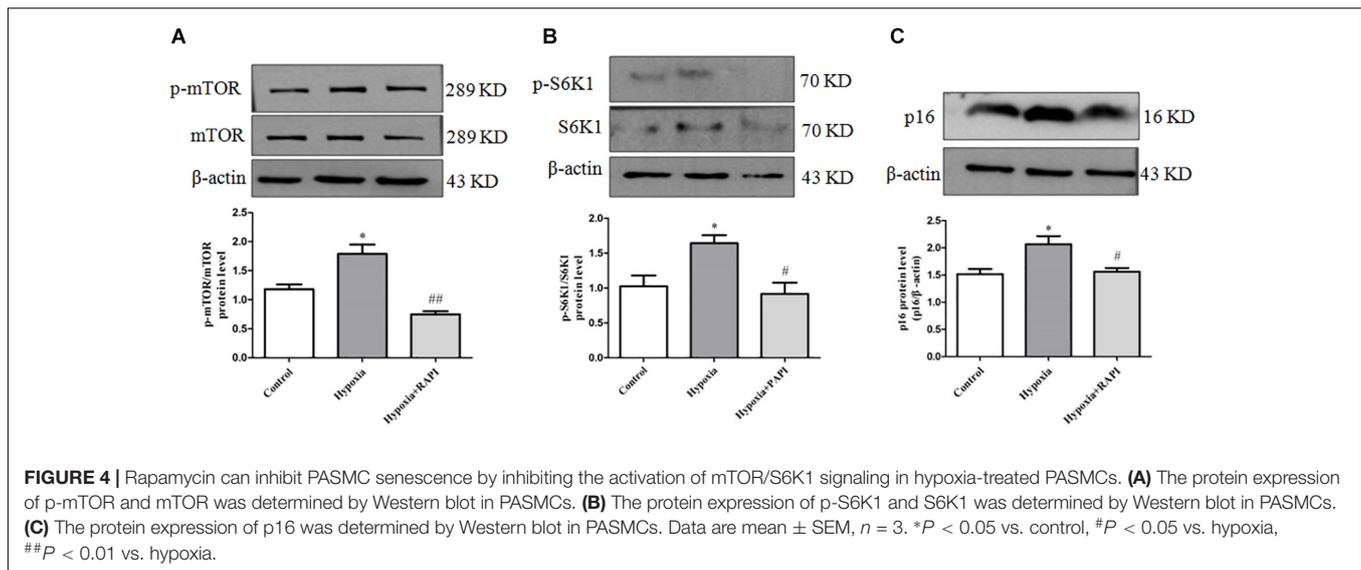

In order to further explore the regulation effect of mTOR on PSMC senescence, we transfected primary PSMCs with

mTOR siRNA (25, 50, 100 nM), observing that mTOR siRNA suppressed markedly the proliferation of PSMCs in hypoxia-treated PSMCs (Figure 7A) and also inhibited the mRNA expression of proliferation marker PCNA (Figure 7B), compared with that of the hypoxia group, which suggest that mTOR siRNA could inhibit the proliferation of PSMCs through inhibiting the senescence of PSMCs. Taken together, these data demonstrated that mTOR/S6K1 signaling can promote PSMC senescence and in turn increase hypoxia-induced proliferation of PSMCs.

DISCUSSION

The pathogenesis of PH is very complex and is a pathophysiological process involving multiple factors. The occurrence of pulmonary vascular remodeling in PH involves a variety of cells (endothelial cell origin, mesangial cell origin, smooth muscle cell itself proliferation origin) (Deng et al., 2015; Ranchoux et al., 2015; Volz et al., 2015), cytokines, and inflammatory factors (IL-6, FGF-2, TGF- β , etc.) (Kim et al., 2015; Simpson et al., 2020) and involves a variety of pathways, such as TGF β , ET1, NO, FGF-2, BMP-ID pathway, TGF β /BMPs-Smad pathway (Abe et al., 2010; Dromparis et al., 2013; Bochenek et al., 2020; Hodgson et al., 2020). Studies have confirmed that PSMC proliferation plays an important role in the occurrence and development of pulmonary vascular remodeling in PH. However, what factors lead to PSMC proliferation and promote pulmonary vascular remodeling in PH are not fully understood. Our study reveals the pathophysiological mechanism of PH from a new perspective and discusses the important role of PSMC senescence as a new pathophysiological mechanism of PH, to explore the important role of PSMC senescence in hypoxia-induced PH and the mechanism of senescence PSMC in secretion of IL-6 promoting PSMC proliferation. On this basis, we elucidate that mTOR/S6K1 pathway can increase PSMC senescence and promote PSMC proliferation in HPH. It will have an exploratory experimental foundation for revealing the pathogenesis of PH and controlling the development of PH and expand a new idea for the prevention and treatment of PH.

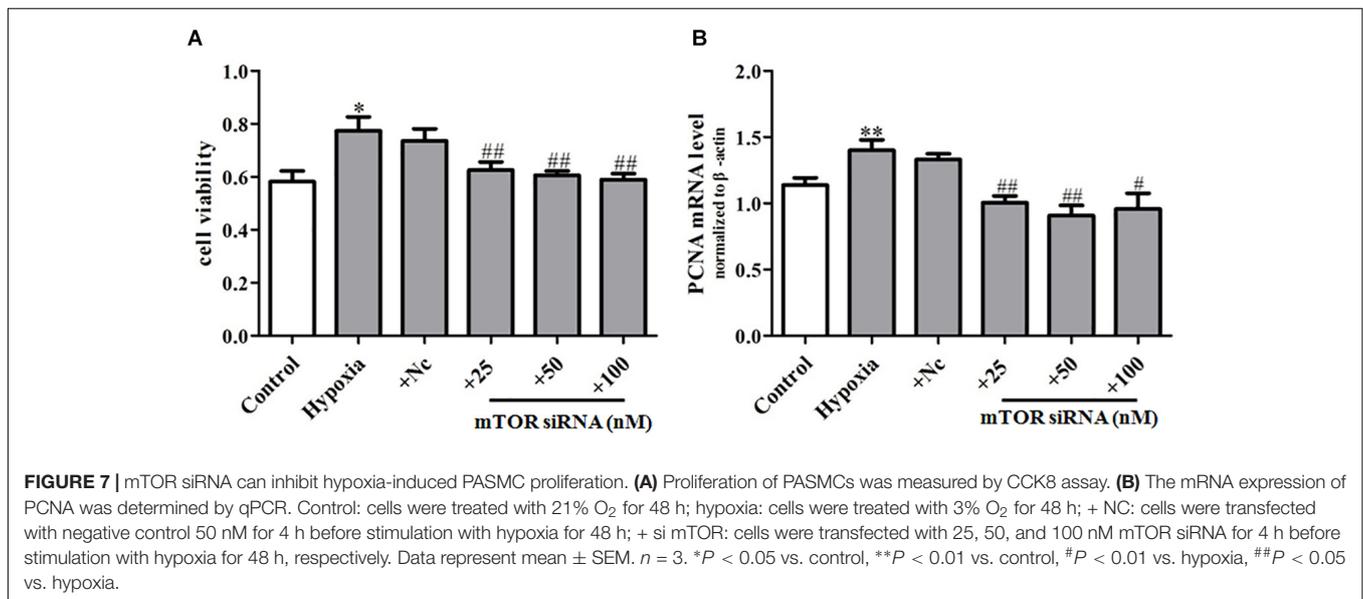

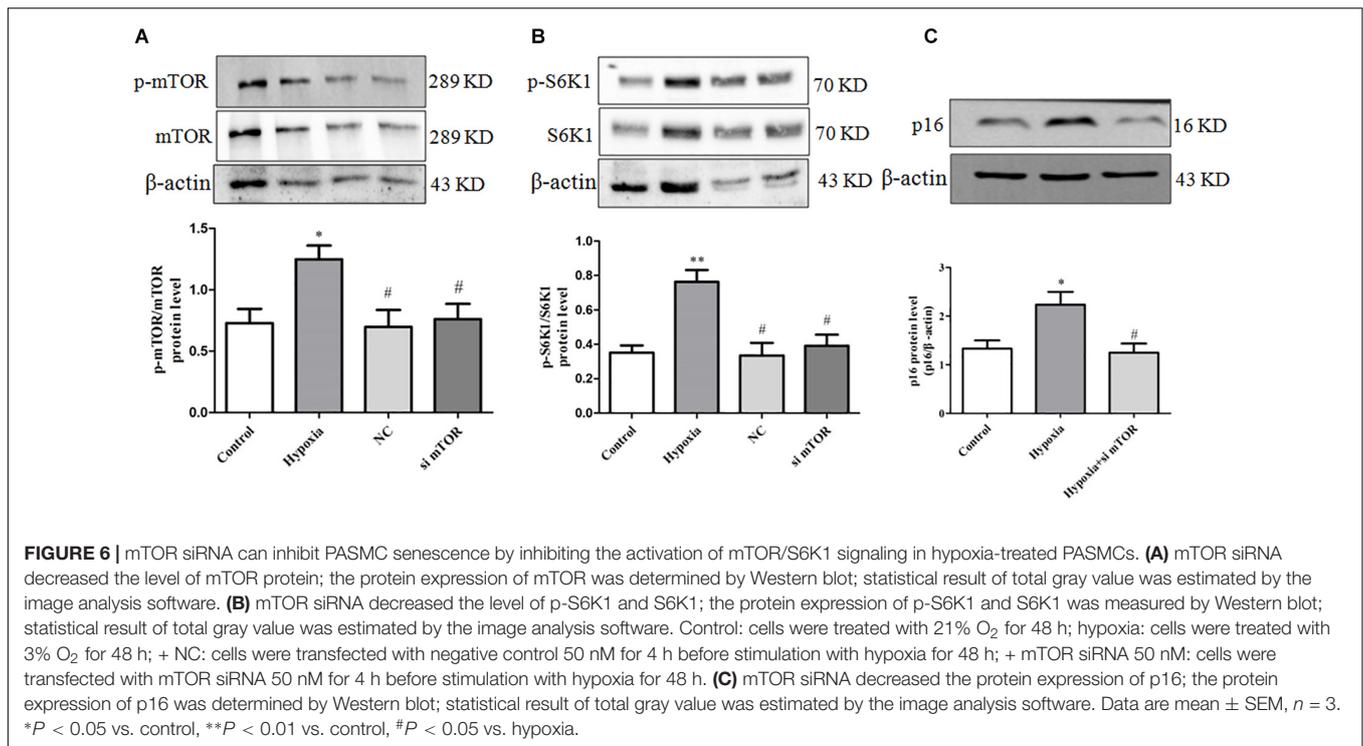

Studies have confirmed that SASP is a secretion composed of a variety of proinflammatory factors, metalloproteinases, and growth factors (Dorr et al., 2013). The secretion of SASP can change the tissue microenvironment and lead to pathological changes of adjacent cells, thus promoting the progress of the disease (Koobatian et al., 2015). Recent clinical studies have found that PSMC senescence is significantly increased in patients with COPD, but the specific mechanism has not been elucidated (Noureddine et al., 2011). Our study results show that PSMC senescence may play an important role in the hypoxia-induced proliferation of PSMCs. In order to explore the role of PSMC senescence in hypoxia-induced proliferation of PSMCs, we used hypoxia-treated primary PSMCs, to detect the changes of β -galactosidase activity and the expression of p21 and p16 protein in hypoxia-induced PSMC proliferation. Our results showed that hypoxia can promote the number of β -galactosidase positive cells and the expression of senescence marker p21, p16 protein up-regulated in hypoxia-induced PSMCs. The above

studies show that PASC senescence is increased significantly in hypoxia-induced PASC proliferation.

As hypoxia can promote PASC senescence, what role does PASC senescence play in hypoxia-induced PASC proliferation? The study found that senescent cells produce a variety of cytokines (SASP), including IL-6, IL-8, TNF- α , and MCP-1, which promote the proliferation of adjacent cells in an autocrine or paracrine manner (Mistriotis and Andreadis, 2017). Previous studies have found that senescence aortic smooth muscle cells promote the development of atherosclerosis by secreting SASP (IL-1 α) (Gardner et al., 2015). Noureddine et al. (2011) found that the IL-6 secretion of senescence PASCs in COPD can regulate PASC proliferation. Therefore, we speculate that IL-6 may be involved in the regulation of PASC proliferation in hypoxia-treated PASCs. To confirm whether IL-6 is involved in PASC proliferation, first, the level of IL-1 β , TGF- β , IL-6, IL-8, MCP-1, and

TNF- α in hypoxia-induced PASCs was screened. The results showed that the level of IL-6 in hypoxia-promoting PASC senescence was significantly increased in hypoxia-induced PASC proliferation. These results indicate that IL-6 may play a more important role than other cytokines in hypoxia-induced PASC proliferation. Our results found that hypoxia promotes PASC senescence at the same time; the level of IL-6 in the culture supernatant was up-regulated, suggesting that the senescence PASCs can promote the secretion of cytokine IL-6 in hypoxia-induced PASC proliferation. To further determine the role of IL-6 in hypoxia-induced PASC proliferation, AX-024 of IL-6 inhibitors was used to block IL-6 secretion in hypoxia-induced PASC proliferation. The results showed that the secretion of IL-6 in the supernatant of cells decreased significantly after blocking IL-6 secretion, and PASC proliferation was significantly inhibited in hypoxia-treated PASCs. Based on the above research, we suggest

that senescence PSMCs promote the abnormal proliferation of PSMCs through secretion of IL-6 and promote the occurrence of PH.

As senescence of PSMCs plays an important role in hypoxia-induced PSMC proliferation, however, what factors (upstream pathways) affect PSMC senescence in hypoxia-induced PSMC proliferation are another important issue that we focus on. In order to clarify the upstream regulatory pathways of PSMC senescence in the process of PH, we reviewed some literature and conducted key preliminary experiments. Studies have

shown that mTOR regulates the senescence of IMR90 cells by regulating SASP (Herranz et al., 2015). Christy et al. (2015) also found that the interaction between P53 and mTOR could affect the senescence of fibroblasts. In addition, Yang et al. (2014) reported that 14,15-epoxidated dicastrienoglyceric acid participated in the regulation of endothelial cell senescence via mTOR. These results suggest that mTOR may be involved in the regulation of vascular cells senescence. Our key preliminary results indicated that hypoxia promoted the senescence of PSMCs accompanied with increasing of p-mTOR levels. The

above results suggest that mTOR may be involved in regulating the senescence of PSMCs. Rapamycin, an mTOR-specific inhibitor, was further used to treat PSMCs. The results showed that rapamycin significantly inhibited the increasing of PSMC senescence, reduced the protein level of p-mTOR, and then inhibited PSMC proliferation in hypoxia-induced PSMCs. After further treatment with mTOR siRNA in hypoxia-induced PSMC proliferation, mTOR siRNA could significantly inhibit the expression of mTOR, which in turn inhibited the expression of P16 and then inhibited hypoxia-induced PSMC proliferation. These results support that mTOR plays an important role in promoting PSMC senescence and thus promotes hypoxia-induced PSMC proliferation.

Ribosomal protein S6 kinase 1 (S6K1) is an important effector protein downstream of mTOR, which has Ser/Thr kinase activity and mediates protein synthesis, mRNA processing, cell growth, and survival (Um et al., 2004; Yuan et al., 2013). Studies have shown that abnormal mTORC1-S6K1 signaling pathway leads to numerous pathological changes, including diabetes, obesity, cancer, organ hypertrophy, and senescence-related diseases (Cornu et al., 2013). Studies have shown that down-regulation of the mTORC1-S6K1 signaling pathway can prolong the life cycle of mice (Liao et al., 2017). In addition, knockout of rps6KBL (encodes S6K1) in mice was discovered to extend the lifespan of female mice (Selman et al., 2009). In our study, we found that S6K1 is activated in hypoxia-promoted PSMC senescence, and rapamycin (the mTOR inhibitor) can inhibit the activation of S6K1, in turn inhibiting the senescence of PSMCs and then inhibiting the hypoxia-induced PSMC proliferation. mTOR siRNA also significantly inhibited the activation of S6K1, inhibited the PSMC senescence, and then inhibited hypoxia-induced PSMC proliferation, which was consistent with the effect of rapamycin. These results suggest that the mTOR/S6K1 pathway is involved in the regulation of PSMC senescence in hypoxia-induced PSMC proliferation and thereby promotes PSMC proliferation in PH.

Our results reveal PSMC senescence is a key role in hypoxia-induced PSMC proliferation. We found that PSMC senescence can promote hypoxia-induced PSMC proliferation through paracrine IL-6, and on this basis, we have clarified that mTOR/S6K1 pathway can accelerate PSMC senescence and in turn promote the PSMC proliferation in hypoxia-induced PSMCs. Our research will help to further reveal the

pathogenesis of PH and provide a new target for seeking new drugs against PH.

DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

ETHICS STATEMENT

The animal study was reviewed and approved by the Laboratory Animal Center, University of South China. Written informed consent was obtained from the individual(s), and minor(s)' legal guardian/next of kin, for the publication of any potentially identifiable images or data included in this article.

AUTHOR CONTRIBUTIONS

Z-SJ and A-PW contributed to the conception of the study. A-PW, YT, S-XG, and X-FM contributed significantly to analysis and manuscript preparation. A-PW, FY, and J-HS performed the data analyses and wrote the manuscript. Z-SJ, QG, and X-PQ helped perform the analysis with constructive discussions. FY, J-HS, and WC did all the experiments. FY did a lot of experiments. QG analyzed and arranged the experiment data and helped perform the analysis with constructive discussions. All authors contributed to the article and approved the submitted version.

FUNDING

This project was financed by the National Key Research and Development Program of China (2019YFA0801601 to Z-SJ), the National Natural Science Foundation of China (grant numbers 91839103 to Z-SJ, 81600040 to A-PW, 31871169 to YT, and 81670053 to QG), Innovation guidance project of Hunan (grant numbers 2018SK51606 to S-XG and 2018SK51704 to X-FM), the province Natural Science Foundation of Hunan (grant number 2020JJ8032 to YT), and Key project of education department of Hunan (grant number 18A243 to A-PW).
