About Frontiers

Frontiers is more than just an open access publisher of scholarly articles: it is a pioneering approach to the world of academia, radically improving the way scholarly research is managed. The grand vision of Frontiers is a world where all people have an equal opportunity to seek, share and generate knowledge. Frontiers provides immediate and permanent online open access to all its publications, but this alone is not enough to realize our grand goals.

Frontiers journal series

The Frontiers journal series is a multi-tier and interdisciplinary set of open-access, online journals, promising a paradigm shift from the current review, selection and dissemination processes in academic publishing. All Frontiers journals are driven by researchers for researchers; therefore, they constitute a service to the scholarly community. At the same time, the *Frontiers journal series* operates on a revolutionary invention, the tiered publishing system, initially addressing specific communities of scholars, and gradually climbing up to broader public understanding, thus serving the interests of the lay society, too.

Dedication to quality

Each Frontiers article is a landmark of the highest quality, thanks to genuinely collaborative interactions between authors and review editors, who include some of the world's best academicians. Research must be certified by peers before entering a stream of knowledge that may eventually reach the public - and shape society; therefore, Frontiers only applies the most rigorous and unbiased reviews. Frontiers revolutionizes research publishing by freely delivering the most outstanding research, evaluated with no bias from both the academic and social point of view. By applying the most advanced information technologies, Frontiers is catapulting scholarly publishing into a new generation.

What are Frontiers Research Topics?

Frontiers Research Topics are very popular trademarks of the *Frontiers journals series*: they are collections of at least ten articles, all centered on a particular subject. With their unique mix of varied contributions from Original Research to Review Articles, Frontiers Research Topics unify the most influential researchers, the latest key findings and historical advances in a hot research area.

Find out more on how to host your own Frontiers Research Topic or contribute to one as an author by contacting the Frontiers editorial office: frontiersin.org/about/contact

Editorial on the Research Topic

Genetics of inflammatory and immune diseases

1 Introduction

Inflammatory and immune diseases encompass a spectrum of conditions, including inflammatory bowel disease, systemic lupus erythematosus, rheumatoid arthritis, psoriasis, and atopic dermatitis (Hodson, 2016; Sroka-Tomaszewska and Magdalena, 2021; Kiriakidou and Ching, 2020). These disorders are characterized by presumed pathomechanisms involving inflammatory and immune systems, frequently exhibiting a significant genetic predisposition. Over the past few decades, genetic studies, particularly genome-wide association studies (GWAS), have identified hundreds of genetic variants robustly associated with these diseases (Klein et al., 2005). The rapid accumulation of GWAS data has broadened opportunities for biologists to discover new disease-associated variants and gain insights into the mechanisms underlying complex human diseases (Wang et al., 2016; Sun et al., 2019; Wang et al., 2021). Although GWAS is a powerful tool, it encounters challenges in precisely pinpointing candidate disease risk genes. In response to these challenges, several post-GWAS methods have emerged, including Transcriptome-Wide Association Studies (TWAS) (Gusev et al., 2016) and Mendelian Randomization (MR) (Bowden and Holmes, 2019). These methods serve as potent tools for identifying candidate disease risk genes, providing benefits such as enhanced statistical power, improved interpretability, and reduced computational costs. Importantly, the exploration of genetic mechanisms (Stikker et al., 2023; Sun et al., 2016), experimental integration research (Xia et al., 2022), multi-omics studies (Husin et al., 2017), and advancements in sequencing technology (Mi et al., 2022) has further contributed to new biological insights into the mechanisms of inflammation and immune disorders. These findings have the potential to identify drug targets of interest.

2 Overview of contributions

The identification of disease-causing variants is crucial for enhancing our understanding of disease pathogenesis and expediting the discovery of diagnostic biomarkers for inflammatory and immune disorders. Fang et al. reported a case study revealing a novel heterozygous variant (c.934G>T, p. Glu312Ter) in the MSN gene associated with X-linked moesin-associated immunodeficiency (X-MAID), identified through whole exome sequencing (WES) and trio analysis. This study broadened the spectrum of MSN mutations linked to immunodeficiency. Li et al. conducted an integrated bioinformatics analysis of 30 patients with systemic lupus erythematosus (SLE) to identify key genes in CD4⁺ T cells, uncovering six novel biomarkers that could contribute to the diagnosis and treatment of SLE. Fu et al. identified immune biomarkers associated with basement membranes in idiopathic pulmonary fibrosis (IPF) through integrated bioinformatics and Pan-cancer analysis. The study pinpointed immune-related hub genes that could serve as potential targets for intervention in various diseases, including IPF and cancer. Additionally, Tang et al. utilized genome sequencing analysis (WGS), meta-analyses, and replication analyses to discover a rare gain-of-function frameshift variant in SIRPB1 associated with Crohn's disease (CD) in Han Chinese patients. The study also investigated the functional mechanism of SIRPB1 and its downstream inflammatory pathways in CD.

The integration of experimental studies with multi-omics studies holds immense potential for unraveling the intricate mechanisms underlying diseases. Yin et al. integrated experimental and transcriptomic approaches, revealing the involvement of interleukin enhancer binding factor 2 (ILF2) and KLHDC7B-DT in the hyperproliferation of keratinocytes and skin inflammation in psoriasis. Notably, ILF2 operates in a KLHDC7B-DT-dependent manner. Similarly, Yan et al. integrated experimental and transcriptomic data to elucidate the potential involvement of serum extracellular vesicles (EVs) in the activation of keratinocytes through loaded miRNAs in psoriasis. Specific miRNAs, such as miR-1305 and miR-6785-5p within serum EVs, were identified as potential contributors to psoriasis. Duan et al. adopted an integrative approach, combining experimental and bioinformatics analyses of 38 samples, to reveal a potential regulatory mechanism of m6A modification in the immune microenvironment of osteoarthritis (OA). This not only provides insights for OA treatment but also addresses a research gap in this field. Furthermore, Ribeiro et al. employed an integrated approach combining experimental and bioinformatics analyses to reveal the global haplotype-specific 3-dimensional chromatin looping architecture. This architecture significantly influences local allelic BLK and FAM167A gene expression, offering mechanistic details on how regional variants controlling the BLK promoter may impact disease risk.

The current study explores the genetic associations and pathogenesis of inflammatory and immune diseases through the application of GWAS and other analytical approaches. Elghzaly et al. performed a GWAS in an admixed Egyptian population, revealing novel genetic associations and providing insights into the pathogenesis of SLE. Their work contributes to an enhanced understanding of the genetic factors underlying this autoimmune

condition. In a related study, Zhang et al. employed multifactor dimensionality reduction (MDR) analysis and meta-analysis techniques to elucidate the interaction between ERAP1 and IFIH1 in influencing the development of psoriasis. This approach provides valuable insights into the complex interplay of genetic factors contributing to the pathophysiology of psoriasis. Bui et al. conducted an investigation into the contributions of both HLA and non-HLA factors to clinical phenotypes within the Newfoundland psoriasis cohort. Utilizing a partitioned 88-loci psoriasis Genetic Risk Score (GRS), they successfully clarified the intricate relationship between HLA and non-HLA components of the GRS with crucial clinical features of psoriasis.

Addressing the challenging task of distinguishing causal signals from mere associations in GWAS poses a substantial challenge. To address this challenge, various methods including fine mapping, MR, and TWAS have emerged, offering avenues to translate GWAS findings into a functional understanding of associated traits. Lee et al. employed meticulous fine mapping to identify the MHC locus variant linked to late-onset asthma across diverse race/ethnicity-stratified populations. This precision enhances our understanding of the genetic basis of asthma and holds promise for the development of precise, targeted treatments tailored to specific demographic groups. Zhao et al. employed a different approach by utilizing circulating cytokines and conducting a two-sample MR analysis to identify causal cytokines associated with the risk of psoriasis vulgaris. This unveiled potential therapeutic targets and shed light on the underlying genetic factors contributing to the development of this dermatological condition. Yang et al. investigated genetically regulated 25OHD concentrations through a meta-analysis and MR study, establishing a causal link between genetically regulated 25OHD concentrations and the risk of chronic obstructive pulmonary disease (COPD). This insight provides a foundation for understanding the genetic underpinnings of COPD and may inform preventive strategies. Zhu et al. conducted a comprehensive strategy involving TWAS and multi-tissue interaction analyses. Their work unveiled candidate susceptibility genes related to respiratory infectious diseases, offering valuable insights at the genetic level and potentially informing future interventions and therapies.

Numerous studies highlighted in this Research Topic have explored diverse phenotypic anchoring strategies to establish genotype-phenotype associations in the realm of inflammatory and immune diseases. In a comprehensive genotype-phenotype association study, Chen et al. employed a multifaceted approach, incorporating clinical characteristics, *in silico* analysis, and intervention. Their investigation led to the identification of two novel compound heterozygous mutations in TTC7A, a groundbreaking discovery marking the first instance of these mutations observed in mainland China. These mutations were associated with neonatal-onset Inflammatory Bowel Disease-Combined Immunodeficiency (IBD-CID) and linked to a poor prognosis. Similarly, Xu et al. delved into the realm of congenital pseudarthrosis of the tibia (CPT) combined with neurofibromatosis type 1, employing a novel NF1 mutation. Their study utilized a combination of clinical characteristics and *in silico* analysis to unravel the intricacies of this distinctive genotype-phenotype association. This research adds valuable insights into the understanding of the complex interplay between genetic

mutations and clinical manifestations in the realm of inflammatory and immune diseases.

Mini-reviews summarizing reported genetic variants, especially in the realm of inflammatory and immune diseases, serve as a valuable approach for hypothesis generation and deepening our understanding of underlying molecular mechanisms. Wang et al. conducted a review focusing on the roles of the AIM2 gene and AIM2 inflammasome in the pathogenesis and treatment of psoriasis. This mini-review aims to provide not only a comprehensive overview but also new insights into the functions of the AIM2 gene and AIM2 inflammasome for psoriasis.

3 Conclusion

Collectively, these articles unveil the genetic foundations of inflammatory and immune diseases. They not only elucidate the mechanisms underlying genetic associations but also uncover new therapeutic targets through the comprehensive application of GWAS, both analytically and experimentally. Post-GWAS, these studies integrate analytics and experiments to deepen our understanding of genetic mechanisms, leveraging advanced sequencing technologies. In doing so, these contributions stand as valuable knowledge resources for future medical research and clinical applications. By offering insights into the intricate genetic landscape of inflammatory and immune diseases, these studies contribute significantly to the ongoing advancement of medical knowledge, fostering the potential for innovative treatments and improved clinical outcomes.

Contributes to Hyperproliferation of
Keratinocytes and Skin Inflammation in
a KLHDC7B-DT-Dependent Manner
in Psoriasis.
Front. Genet. 13:890624.
doi: 10.3389/fgene.2022.890624

Background: The extensive involvement of interleukin enhancer binding factor 2 (ILF2) in RNA stability and the inflammatory response is well documented. Aberrant long noncoding RNA (lncRNA) expression contributes to the pathogenesis of psoriasis. However, little is known about the role of ILF2 in psoriasis.

Objective: To investigate the role of ILF2 and KLHDC7B-DT in psoriasis.

Methods: lncRNA expression in psoriatic tissues was measured by lncRNA microarray and qRT-PCR. Normal human epidermal keratinocytes (NHEKs), HaCaT cells, and Ker-CT cells stimulated with M5 (IL-17A, IL-22, IL-1 α , oncostatin M, and TNF- α) were used to establish a psoriasis model *in vitro*. Fluorescence *in situ* hybridization was used to detect the distribution of KLHDC7B-DT and ILF2 in keratinocytes. The proliferative effects of KLHDC7B-DT and ILF2 on keratinocytes were demonstrated by EdU assay and flow cytometry. ELISA was used to detect the secretion levels of cytokines. RNA pull-down and RNA immunoprecipitation (RIP) were used to detect the direct binding of KLHDC7B-DT with ILF2. Western blotting was used to detect the proteins related to STAT3/JNK signalling pathways.

Results: ILF2 and KLHDC7B-DT were significantly overexpressed in psoriatic tissues and M5-induced keratinocytes. KLHDC7B-DT promoted the proliferation of keratinocytes and induced the secretion of IL-6 and IL-8. KLHDC7B-DT could directly bind to ILF2 and activate the STAT3 and JNK signalling pathways. KLHDC7B-DT expression was regulated by ILF2. M5-induced proliferation and inflammatory cytokine secretion in keratinocytes was inhibited after ILF2 knockdown. Furthermore, we found that ILF2 promoted keratinocyte proliferation and the inflammatory response in a KLHDC7B-DT-dependent manner.

Conclusions: ILF2 and KLHDC7B-DT are involved in the hyperproliferation of keratinocytes and skin inflammation in psoriasis. In addition, ILF2 functions in a KLHDC7B-DT-dependent manner.

Keywords: ILF2, KLHDC7B-DT, psoriasis, proliferation, inflammation

INTRODUCTION

Psoriasis is a common immune-mediated chronic inflammatory skin disease characterized by red, scaly skin plaques (Boehncke and Schön, 2015; Srivastava et al., 2017). Recent studies have shown that immune, genetic and environmental factors are all responsible for the pathogenesis of psoriasis (Nickoloff et al., 2007a; Lin et al., 2011). Accumulating studies have suggested that psoriasis is mainly caused by abnormal crosstalk between keratinocytes and immune cells. Various cytokines secreted by immune cells activate keratinocytes and lead to keratinocyte secretion of proinflammatory cytokines, thereby sustaining the inflammatory response (Albanesi et al., 2005; Albanesi et al., 2007).

Long noncoding RNA (lncRNA) is a noncoding RNA with a length of more than 200 nucleotides and limited protein-encoding abilities (Fatica and Bozzoni, 2014; Iyer et al., 2015). Recent studies have confirmed that some inflammatory diseases, such as psoriasis, rheumatoid arthritis (RA) (Wu et al., 2015), Crohn's disease (CD) and ulcerative colitis (UC) (Mirza et al., 2015), and multiple sclerosis (MS) (Santoro et al., 2016), show abnormal lncRNA expression. Psoriasis susceptibility-related RNA gene induced by stress (PRINS) was initially identified as a biomarker of genetic susceptibility to psoriasis (Szegedi et al., 2010). Our previous study confirmed that lncRNA MSX2P1 was involved in the pathogenesis of psoriasis by directly binding to miR-6731-5p and activating S100A7 (Qiao et al., 2018). These findings demonstrate that differentially expressed lncRNAs contribute to the pathogenesis of psoriasis.

In this study, we performed a lncRNA microarray and found 2,194 differentially expressed lncRNAs (1,123 upregulated and 1,071 downregulated; fold change ≥ 2 and $p < 0.05$). The microarray results showed that ENST00000609178, also named KLHDC7B-DT (NCBI Gene ID: 105373098), was upregulated (fold change of 17.05) in psoriatic lesions compared to normal tissues. Previous reports have shown that KLHDC7B-DT activates STAT3 signalling by inducing IL-6 secretion (Li et al., 2021). STAT3 signalling and IL-6 are closely related to the pathogenesis of psoriasis, and we hypothesized that KLHDC7B-DT might participate in regulating the inflammatory response and be involved in the pathogenesis of psoriasis.

ILF2, also known as nuclear factor 45 (NF45), is crucial for cell growth and the inflammatory response (Du et al., 2019). Recent studies have shown that ILF2 can promote cell proliferation and the inflammatory response (Jia et al., 2020; Zhang et al., 2021). ILF2 forms a complex with the 90 kDa interleukin enhancer binding factor 3 (NF90, ILF3) (Zhao et al., 2005; Kuwano et al., 2008). A previous study confirmed that lncRNAs could promote cell proliferation through association with the NF45/NF90 complex (Huang et al., 2020). In the present study, we found that both ILF2 and KLHDC7B-DT were overexpressed in psoriatic lesions as well as M5-treated keratinocytes compared with controls. KLHDC7B-DT could directly bind with ILF2, and its expression was regulated by ILF2. As KLHDC7B-DT and ILF2 were significantly overexpressed in psoriatic lesions

and closely related to inflammatory responses, KLHDC7B-DT and ILF2 were selected as potential candidates for this study.

Here, we explored the role of ILF2 and KLHDC7B-DT in the pathogenesis of psoriasis for the first time. We verified the effects of ILF2 and KLHDC7B-DT on the proliferation of keratinocytes and the secretion of IL-6 and IL-8. In addition, we showed that KLHDC7B-DT promoted the proliferation of keratinocytes and induced the secretion of IL-6 and IL-8 by activating the STAT3 and JNK signalling pathways. Furthermore, we found that ILF2 functions in a KLHDC7B-DT-dependent manner in psoriasis. Our findings provide a potential therapeutic strategy for psoriasis.

MATERIALS AND METHODS

Patient and Tissue Sample Collection

Ten samples were collected from patients with vulgaris psoriasis (6 males and 4 females; aged 24–49 years) from Qilu Hospital of Shandong University. The patients had not received systemic therapy or topical treatment within 3 months. In addition, 10 normal tissues were collected from healthy volunteers (6 males and 4 females; aged 22–40 years). The healthy subjects had no family history of psoriasis or any other autoimmune diseases. We separated the epidermis from psoriatic lesions and healthy control tissues for further experiments. This study was approved by the Ethics Committee of Shandong University, Qilu Hospital (Jinan, China), and all patients provided written informed consent.

lncRNA Microarray

The microarray was performed by Shanghai shbio Biotechnology Co., Ltd. The results were detected by an Agilent microarray scanner and analyzed by Agilent feature extraction software.

Cell Isolation and Culture

Purified normal human epidermal keratinocytes (NHEKs) were obtained after 2–3 generations. HaCaT cells (Procell Life Science & Technology Co., Ltd.) were cultured in Dulbecco's modified Eagle's medium (DMEM) (Gibco, United States) containing 10% foetal bovine serum (FBS) (Sangon Biotech, China), 100 $\mu\text{g/ml}$ streptomycin and 100 U/ml penicillin. Ker-CT (CRL4048TM) from American Type Culture Collection (ATCC) was cultured in KGMGoldTM BulletKitTM (Lonza 00192060). All cells were incubated in a humidified chamber at 37°C with 5% CO₂.

RNA Fluorescence *In situ* Hybridization

KLHDC7B-DT probes (5'-CY3-TAACGCTCTTTCAGTCAGGTGTTCCCC, GenePharma) were used for hybridization. DAPI (Servicebio, G1012) was used for nuclear staining.

Construction of the Psoriatic Cell Model

When cell confluence reached approximately 60–70%, cells were starved in serum-free DMEM for 12 h. Then, M5 (10 ng/ml final concentration; PeproTech), a cocktail of cytokines, was used to

treat NHEKs, HaCaT cells, and Ker-CT cells in serum-free DMEM to induce psoriatic inflammation-like conditions for another 24 h. Controls were left untreated.

Cell Transfection

For gene knockdown, small interfering RNAs (siRNAs) (GenePharma) of KLHDC7B-DT and ILF2 were transferred into HaCaT and Ker-CT cells using Lipofectamine 2000 transfection reagent (Invitrogen, Carlsbad, United States). For gene overexpression, HaCaT and Ker-CT cells were transfected with the eukaryotic expression vector pcDNA3.1 (GenePharma, **Supplementary Figure S1**) with jet PRIME transfection reagent (Polyplus, United States). The oligonucleotide sequences are shown in **Table 1**.

qRT-PCR

qRT-PCR was performed as described in our previous experiments (Yan et al., 2019). The relative gene expression was normalized to GAPDH or U6 and calculated using the 2^{-ΔΔCt} method. The primer sequences are summarized in **Table 2**.

Western Blotting

Western blotting was performed as described in our previous experiments (Jiang et al., 2017; Zhao et al., 2017). The following primary antibodies were used in this study: GAPDH, p-JNK1/2, JNK1/2, p-STAT3, STAT3 (all from Cell Signaling Technology, Boston, United States), cyclin D1, BCL-xL (both from Abcam, Cambridge, United Kingdom), and ILF2 (from ZenBioScience, China).

EdU Incorporation Assay

The EdU (5-ethynyl-2'-deoxyuridine) incorporation assay was performed using a Cell-Light EdU DNA Cell Proliferation Kit (RiboBio, Guangzhou, China).

Flow Cytometry Analysis

Cell cycle and apoptosis analyses were performed by flow cytometry using a DNA content quantitation assay kit (Solarbio, Beijing, China) and an Annexin V-fluorescein

isothiocyanate (FITC) apoptosis measurement kit (BD Biosciences, United States).

Enzyme-Linked Immunosorbent Assay

After 24 h of transfection as described above, cells were stimulated with M5, and culture supernatants were collected after 12 h. The secretion of IL-6 and IL-8 was measured using specific ELISA kits (Elabscience, China). The absorbance at 450 nm was measured with a microplate reader (BioTek, United States).

RNA Pull-Down Assays and Mass Spectrometry Analyses

The interaction between KLHDC7B-DT and RNA-binding protein was detected by a Pierce Magnetic RNA-Protein Pull-Down Kit (Thermo Fisher Scientific, United States). A Fast Digest Hind III Kit (Thermo Scientific) and MEGA Script Kit (Life Technologies) were used for digestion, linearization, and transcription. Biotin-labelled KLHDC7B-DT was incubated with total cell lysates of HaCaT cells, and eluted proteins were purified. The sequences of biotin-labelled KLHDC7B-DT are shown in **Supplementary Table S1**. Finally, interacting proteins were identified by mass spectrometry and Western blotting.

RNA Immunoprecipitation Assay

RIP was carried out using a Magna RIP Kit (Millipore, Billerica, MA, United States). HaCaT and Ker-CT cells were lysed with RNA lysis buffer, and cell lysates were incubated with RIP buffer containing magnetic beads conjugated to anti-ILF2 (ZenBioScience, #382994) or negative control IgG antibody (Millipore, Billerica, MA, United States) for 4 h at 4°C. Then, qRT-PCR and agarose electrophoresis were implemented to detect RNA. The sequences of primers for qRT-PCR are shown in **Supplementary Table S2**.

Immunohistochemistry

IHC was performed as previously described (Jiang et al., 2017; Zhao et al., 2017). Primary antibodies against ILF2

(ZenBioScience, #382994) were used in this study. IHC staining was quantified using H-scores, which incorporate the staining intensity and the percentage of positively-stained cells (range 0–100%).

Immunofluorescence

Immunofluorescence was performed according to the manufacturer's directions. Samples were analysed using a Zeiss LSM710 Confocal Laser Scanning Microscope (Carl Zeiss, Oberkochen, Germany).

Statistical Analysis

Data from at least three independent experiments are presented as the means \pm standard deviation (SD). Statistical significance was analysed using GraphPad Prism (version 6, San Diego, United States). Differences between the two groups were analysed using Student's *t* test. $p < 0.05$ was considered statistically significant.

RESULTS

KLHDC7B-DT Is Upregulated in Psoriatic Tissues and M5-Induced Keratinocytes

To identify new lncRNAs associated with the pathogenesis of psoriasis, a lncRNA microarray was performed ($n = 3$, accession number: GSE181318). The microarray results showed that

KLHDC7B-DT was one of the most significantly upregulated lncRNAs in psoriatic tissues, which was also confirmed by qRT-PCR (Figures 1A,B). Subsequently, an *in vitro* psoriasis model was established by stimulating keratinocytes with M5. As expected, the expression of KLHDC7B-DT was increased in M5-treated NHEKs, HaCaT cells, and Ker-CT cells (Figure 1C). FISH assays in HaCaT and Ker-CT cells indicated that KLHDC7B-DT was mainly distributed in the nucleus (Figure 1D). In addition, Sanger sequencing showed that the sequence of the amplified product was consistent with that of the template (Supplementary Figure S2). These results indicated that aberrantly upregulated KLHDC7B-DT expression might be associated with the pathogenesis of psoriasis.

KLHDC7B-DT Regulates Proliferation and Inflammatory Factor Secretion in M5-Induced Keratinocytes

We next investigated the potential biological roles of KLHDC7B-DT in M5-induced keratinocytes. qRT-PCR showed that KLHDC7B-DT expression was significantly suppressed by siRNA in HaCaT and Ker-CT cells (Figure 2A). EdU incorporation assays showed that M5 treatment increased EdU-positive cells, and the proliferation-promoting effect was inhibited by KLHDC7B-DT knockdown (Figure 2B). Cell cycle results indicated that M5 treatment led to a reduced proportion in

the G1 phase and an increased proportion in the S phase, and KLHDC7B-DT knockdown reversed the M5-induced effects (Figure 2C). Moreover, cell apoptosis analysis revealed that M5 treatment suppressed the proportion of early and late apoptotic cells, whereas KLHDC7B-DT knockdown induced a higher proportion of early and late apoptotic cells (Figure 2D). These findings suggested that KLHDC7B-DT regulates the proliferation of keratinocytes in psoriasis.

ELISAs showed that the M5-induced expression of IL-6 and IL-8 was partially reversed after KLHDC7B-DT knockdown in keratinocytes (Figure 2E). Collectively, our data demonstrated that KLHDC7B-DT knockdown reverses M5-induced hyperproliferation and the inflammatory response in keratinocytes, indicating that KLHDC7B-DT might play an important role in psoriasis by regulating the proliferation and inflammatory response of keratinocytes.

Overexpression of KLHDC7B-DT Facilitates Proliferation and Secretion of Inflammatory Factors in Keratinocytes

To further verify the role of KLHDC7B-DT in psoriasis, we stably overexpressed KLHDC7B-DT *via* transfection of a

plasmid into M5-induced HaCaT and Ker-CT cells (Figure 3A). EdU assays showed that HaCaT and Ker-CT cells overexpressing KLHDC7B-DT had more EdU-positive cells (Figure 3B). The cell cycle results demonstrated that KLHDC7B-DT overexpression led to a reduced proportion of cells in the G1 phase and an increased proportion of cells in the S phase (Figure 3C). Moreover, cell apoptosis analysis revealed that KLHDC7B-DT overexpression inhibited the proportion of early and late apoptosis (Figure 3D). Overexpression of KLHDC7B-DT also significantly upregulated the IL-6 and IL-8 protein expression levels in M5-treated HaCaT and Ker-CT cells (Figure 3E). Taken together, these findings demonstrated that KLHDC7B-DT overexpression promotes the proliferation and inflammatory response in M5-induced keratinocytes.

KLHDC7B-DT Binds With the ILF2 Protein and Activates JNK/STAT3 Signalling

To further understand the molecular mechanism by which KLHDC7B-DT regulates proliferation and the inflammatory response in M5-induced keratinocytes, we precipitated synthesized KLHDC7B-DT *in vitro* and subjected it to mass spectrometric identification. RNA pull-down assays in

HaCaT cells showed that several proteins were identified as interacting partners of KLHDC7B-DT (Figure 4A). The binding proteins were further detected and analysed using mass spectrometry, which showed that KLHDC7B-DT could bind to the interacting proteins. Kyoto Encyclopedia of Genes and Genomes analysis suggested that these proteins were involved in the JAK-STAT and MAPK signalling pathways, while Gene Ontology analysis revealed the cell cycle, apoptosis, and inflammation functions of these proteins (Supplementary Figure S3A,B). Based on the mass spectrum assay (Figure 4B), we found that ILF2 was enriched in the KLHDC7B-DT-sense group among the detected proteins. Western blotting validated the existence of ILF2 within the RNA pull-down samples of KLHDC7B-DT in HaCaT cells (Figure 4C). In addition, RIP assays demonstrated the interaction between ILF2 and KLHDC7B-DT in HaCaT and Ker-CT cells (Figure 4D). By detecting the enriched RNA, the amplification band of KLHDC7B-DT was obtained by agarose electrophoresis (Figure 4E).

The expression of ILF2 was detected after KLHDC7B-DT knockdown and overexpression in HaCaT and Ker-CT cells, and no significant differences in ILF2 mRNA or protein

expression were found (Figures 4F,G). To further determine whether ILF2 was involved in the upregulation of KLHDC7B-DT in psoriasis, ILF2 was knocked down in HaCaT and Ker-CT cells. The interference efficiency was verified by qRT-PCR (Supplementary Figure S4) and Western blotting (Figure 4H). Notably, ILF2 knockdown inhibited the expression of KLHDC7B-DT (Figure 4I).

Western blotting showed that the levels of p-STAT3 and p-JNK were significantly decreased after KLHDC7B-DT knockdown. In contrast, the protein levels of p-STAT3 and p-JNK were significantly increased after KLHDC7B-DT overexpression (Figure 4J). These results suggested that KLHDC7B-DT functioned by regulating the STAT3 and JNK signalling pathways in psoriasis.

ILF2 is Upregulated in Psoriatic Tissues and Contributes to the Proliferation and Secretion of Inflammatory Factors in Keratinocytes

Next, we investigated the role of ILF2 in psoriasis. qRT-PCR ($n = 3$) and Western blotting ($n = 3$) demonstrated that ILF2

was overexpressed in psoriatic tissues (Figures 5A,B). We carried out IHC staining to analyze the protein expression of ILF2 in 10-paired psoriatic tissues and normal tissues. The H-score indicated that ILF2 expression was increased in psoriatic tissues in contrast to normal tissues (Figure 5C). The expression of ILF2 was increased in M5-treated HaCaT and Ker-CT cells (Figure 1D). A cell immunofluorescence assay demonstrated that ILF2 was mainly localized in the nucleus of HaCaT cells and Ker-CT cells (Figure 5D). EdU assays showed that ILF2 knockdown inhibited the proliferation of keratinocytes (Figure 6A). Cell cycle analysis showed that ILF2 knockdown increased the proportion of the G1 phase and decreased the proportion of the S phase in keratinocytes (Figure 6B). Annexin-V/PI staining results demonstrated that the proportion of apoptotic cells increased after ILF2 knockdown (Figure 6C). In addition, ELISA analysis showed that the increased protein levels of IL-6 and IL-8 in M5-induced keratinocytes were significantly decreased after ILF2 knockdown (Figure 6D). Collectively, these findings showed that ILF2 knockdown inhibits the proliferation, cell cycle and secretion of inflammatory factors and promotes apoptosis in M5-induced keratinocytes.

ILF2 Promotes Hyperproliferation and Inflammation Through STAT3/JNK Pathways in a KLHDC7B-DT-Dependent Manner

To explore the regulatory mechanism of ILF2 and KLHDC7B-DT in psoriasis, ILF2 siRNA was transfected alone or together with pcDNA-KLHDC7B-DT into M5-treated HaCaT and Ker-CT cells. Then, the proliferation, cell cycle, apoptosis, and inflammatory factor secretion of keratinocytes were detected. The reduced percentage of EdU-positive cells and G1/S growth arrest caused by ILF2 knockdown could be rescued by KLHDC7B-DT overexpression (Figures 6A,B). ILF2 knockdown increased the proportion of apoptotic cells, which was significantly reversed by overexpression of KLHDC7B-DT (Figure 6C). Moreover, the ILF2 knockdown-mediated decrease in IL-6 and IL-8 protein levels was significantly reversed by KLHDC7B-DT overexpression (Figure 6D).

Then, we stably overexpressed ILF2 *via* transfection of a plasmid into M5-induced HaCaT cells. The overexpression efficiency was verified by Western blotting (Supplementary Figure S5). Then pcDNA-ILF2 was transfected alone or together with siKLHDC7B-DT into M5-treated HaCaT cells, the proliferation, cell cycle, apoptosis, and inflammatory factor

FIGURE 5 | ILF2 is highly expressed in psoriatic lesions. **(A)** The mRNA expression level of ILF2 in psoriatic tissues ($n = 3$). **(B)** The protein expression level of ILF2 in psoriatic tissues ($n = 3$). **(C)** The expression of ILF2 in normal and psoriatic tissues was detected by IHC ($n = 10$). The H-score was calculated based on the percentage of ILF2+ cells and staining intensity. **(D)** The expression level of ILF2 in M5-treated HaCaT and Ker-CT cells. **(E)** Subcellular localization of ILF2 in HaCaT and Ker-CT cells. secretion of keratinocytes were detected. The increased percentage of EdU-positive cells and promotion of G1/S transition caused by ILF2 overexpression could be reversed by KLHDC7B-DT knockdown (**Supplementary Figure S6A,B**). ILF2 overexpression decreased the proportion of apoptotic cells, which was significantly rescued by KLHDC7B-DT knockdown (**Supplementary Figure S6C**). Moreover, the ILF2 overexpression-mediated increase in IL-6 and IL-8 protein levels was significantly reversed by KLHDC7B-DT knockdown (**Supplementary Figure S6D**).

As it has been reported that ILF2 is involved in inflammatory responses through the STAT3 and JNK signalling pathways, we investigated whether ILF2 induces phosphorylation of STAT3/JNK in HaCaT and Ker-CT cells. Interestingly, ILF2 knockdown decreased the phosphorylation levels of STAT3/JNK. More importantly, decreased STAT3/JNK phosphorylation after ILF2 knockdown could be reversed by KLHDC7B-DT overexpression (**Figure 6E**). Taken together, the results indicated that ILF2 promotes hyperproliferation and inflammation through STAT3/JNK pathways in a KLHDC7B-DT-dependent manner.

DISCUSSION

Psoriasis is a chronic inflammatory skin disorder (Nickoloff et al., 2007b; Bos, 2007; Boehncke and Sterry, 2009). Keratinocytes actively participate in the initiation and maintenance of psoriatic skin inflammation through the production of various proinflammatory cytokines (Lowes et al., 2014). In this study, we performed a lncRNA microarray, and the results showed that

KLHDC7B-DT was one of the most significantly upregulated lncRNAs in psoriatic tissues. Then, we verified the results in psoriatic lesions and a psoriasis model *in vitro* by stimulating keratinocytes with IL-17A, IL-22, IL-1 α , oncostatin M, and TNF- α (M5) (Rabeony et al., 2014; Li et al., 2019). We found that the expression levels of KLHDC7B-DT, as well as its binding protein ILF2, were upregulated in both skin lesions and psoriasis model keratinocytes, suggesting that KLHDC7B-DT and ILF2 might be involved in the pathogenesis of psoriasis.

lncRNAs have been revealed to participate in the pathogenesis of psoriasis, including MEG3, GAS5, and MIR31HG (Gao et al., 2018; Jia et al., 2019; Ahmed Shehata et al., 2021). Here, we demonstrated that KLHDC7B-DT positively regulates the proliferation of keratinocytes. Cell cycle analysis and Annexin-V/PI staining indicated that KLHDC7B-DT regulates the G1/S transition and cell apoptosis. These results suggested that KLHDC7B-DT might be involved in the pathogenesis of psoriasis by regulating keratinocyte proliferation and apoptosis.

IL-6 and IL-8 have been proven to play important roles in psoriasis (Elder et al., 1992; Yoshinaga et al., 1995). Previous studies also demonstrated that serum levels of proinflammatory cytokines reflect disease activity and treatment response (Grossman et al., 1989; Biasi et al., 1998). In this study, we found that the expression of IL-6 and IL-8 was regulated by KLHDC7B-DT in keratinocytes. Our findings suggested that KLHDC7B-DT contributes to psoriatic skin inflammation by regulating the expression of IL-6 and IL-8.

It has become increasingly clear that the biological functions of lncRNAs are associated with their unique subcellular localization (Carlevaro-Fita and Johnson, 2019). lncRNAs can function by

FIGURE 6 | ILF2 promotes hyperproliferation and inflammation through STAT3/JNK pathways in M5-induced keratinocytes. **(A)** Using an EdU assay, the proliferative effects of M5-induced keratinocytes were detected after transfection with siILF2 and siILF2+pcDNA-KLHDC7B-DT. **(B)** The cell cycle was detected by flow cytometry through PI staining. **(C)** Cell apoptosis was detected by flow cytometry through Annexin-V/PI staining. **(D)** Protein levels of IL-6 and IL-8 were detected by ELISA. **(E)** Activation of the STAT/JNK pathway detected by Western blotting. Data are shown as the means \pm SD, * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$. All experiments were repeated at least three times.

interacting with proteins *via* structural interactions and/or complementary base pairing (Tang et al., 2020). In this study, both ILF2 and KLHDC7B-DT were found to be mainly distributed in the nucleus. Furthermore, we confirmed the interaction between KLHDC7B-DT and ILF2 protein by RNA pull-down and RIP assays. We found that ILF2 acted as the upstream regulator of KLHDC7B-DT and positively regulated its expression. In addition, previous studies reported that ILF2 was involved in inflammatory responses through the STAT3 and JNK inflammatory signalling pathways (Jia et al., 2020). We confirmed that ILF2 was upregulated in psoriatic tissues and M5-induced keratinocytes. Moreover, overexpression of KLHDC7B-DT rescued the effects of ILF2 knockdown on keratinocyte proliferation and cytokine secretion. In contrast, KLHDC7B-DT knockdown reversed the effects of ILF2 overexpression. These results suggested that ILF2 regulates proliferation and the inflammatory response *via* KLHDC7B-DT in keratinocytes.

Furthermore, KEGG and GO analyses showed that proteins binding with KLHDC7B-DT were involved in the JAK-STAT and MAPK signalling pathways. Previous studies have reported that STAT3 and JNK play crucial roles in regulating immune responses and participate in the pathogenesis of psoriasis (Sano et al., 2005; Liang et al., 2019). IL-6 and IL-8 have been proven to play important roles in psoriasis, and both of them can initiate STAT3

and JNK MAPK pathway, thus involving in regulating cell inflammation and proliferation of keratinocytes (Mori et al., 2011; Chen et al., 2015; Fu et al., 2015). Furthermore, KLHDC7B-DT was found to directly bind to the IL-6 promoter activate IL-6 transcription, up-regulate IL-6 expression. Through enhancing IL-6 secretion, KLHDC7B-DT activated STAT3 signaling in PDAC cells (Jia et al., 2020). In addition to the STAT3 signaling pathway, IL-6 also activates the MAPK cascade (Neurath and Finotto, 2011). Our findings showed that KLHDC7B-DT is closely related to the activation of the STAT3 and JNK signalling pathways, and indicated that KLHDC7B-DT activated STAT3 and JNK signaling pathways by promoting IL-6 and IL-8 secretion. Furthermore, overexpression of KLHDC7B-DT rescued the expression of p-STAT3 and p-JNK after ILF2 knockdown, which indicated that ILF2 regulates the STAT3/JNK pathways *via* KLHDC7B-DT. To sum up, our results suggested that ILF2 regulates proliferation and inflammatory reactions *via* the KLHDC7B-DT and STAT3/JNK signalling pathways in keratinocytes.

Although various studies have emphasized the important role of lncRNAs, few have focused on the underlying mechanism driving the abnormal expression of lncRNAs in psoriasis. In the present study, our data demonstrated that upregulated expression of KLHDC7B-DT was associated with high levels of ILF2 in psoriatic tissues.

However, this study was subject to some limitations. Our sample sizes were relatively small, and further investigations with larger samples are required to verify our findings. The expression of KLHDC7B-DT and ILF2 was focused only on psoriasis. Other inflammatory diseases, including atopic dermatitis, should be included to investigate the specificity of the biomarkers.

CONCLUSION

In conclusion, we demonstrated that KLHDC7B-DT and ILF2 are overexpressed in psoriatic skin lesions. Overexpression of KLHDC7B-DT in psoriasis was related to the aberrant expression of ILF2. ILF2 and KLHDC7B-DT were involved in the hyperproliferation of keratinocytes and skin inflammation in psoriasis. In addition, we verified that ILF2 functions in a KLHDC7B-DT-dependent manner.

A Novel Variant of X-Linked Moesin
Gene in a Boy With Inflammatory
Bowel Disease Like Disease-A
Case Report.
Front. Genet. 13:873635.
doi: 10.3389/fgene.2022.873635

Variants in the *MSN* gene were recently reported as the cause of a primary immunodeficiency disease called X-linked moesin-associated immunodeficiency (X-MAID). Hitherto, only 10 patients were reported worldwide. Here, we report a boy who presented with recurrent high fever, oral ulcers, abdominal pain, and hematochezia for over 2 weeks. His serum inflammatory markers were elevated, and colonoscopy showed multiple colon ulcers and terminal ileum ulcers which resemble colitis caused by inflammatory bowel disease. A novel heterozygous variant c.934G>T(p.Glu312Ter) in the *MSN* gene was identified using whole exome sequencing (WES) and trio analysis. Intestinal ulcers were almost healed after inducing therapy with steroids and maintenance treatment of anti-TNF α therapy. We summarized the genotype and phenotype of reported X-MAID patients and presented the patient's unique phenotype in this study. This study also expanded the spectrum of *MSN* mutation-caused immunodeficiency.

Keywords: moesin gene, intestinal ulcer, colitis, very early-onset inflammatory bowel disease, primary immunodeficiency disease

INTRODUCTION

Variants in the moesin (*MSN*) gene were first recognized as a cause of congenital disease in humans in 2016; the resulting disease is referred to as X-linked moesin-associated immunodeficiency (X-MAID, #300988) (Lagresle-Peyrou et al., 2016). Patients with hemizygous mutations in the *MSN* gene present with lymphopenia, hypogammaglobulinemia, and susceptibility to bacterial and viral infections (Lagresle-Peyrou et al., 2016). X-MAID patients also exhibit impaired T-cell proliferation and altered migration and adhesion capacities (Lagresle-Peyrou et al., 2016). *MSN*, ezrin and radixin are members of the ezrin-radixin-moesin (ERM) family. ERM is a cell-structure-related protein that regulates the actin cytoskeleton and plasma membranes (Burns et al., 2017). Although *MSN*, ezrin, and radixin are structurally and functionally similar, they demonstrate different physical functions and expression patterns. Ezrin protein is mostly expressed in epithelial cells, whereas *MSN* predominates in endothelial cells (Berryman et al., 1993). *MSN* and ezrin play important roles in lymphoid cell proliferation, migration and adhesion (Lagresle-Peyrou et al., 2016). *MSN* knockout mice show impaired chemotaxis of T and B lymphocytes (Hirata et al., 2012).

X-MAID is classified as a primary immunodeficiency (PID), and most PIDs are monogenic diseases. In recent years, PIDs have been reported to have a close relationship with very early-onset inflammatory bowel disease (VEOIBD), which is defined as inflammatory bowel disease (IBD) that

occurs before 6 years of age. PIDs that mainly present with IBD-like features belong to monogenic IBD as well. To date, more than 70 genes have been discovered that are associated with monogenic IBD. Some genes reported as associated with immune deficiency or inborn errors of immunity. The majority (>70–80%) of VEOBD patients not have a specific identified causal genetic etiology (Charbit-Henrion et al., 2018). However, the rate of genetic discoveries among VEOBD patients is increasing, especially in the group of infantile onset IBD patients. The well-known genes related to monogenic IBD are *IL10/IL10R*, *XIAP* and *CGD*. Among these genes, the most common variants that lead to VEOBD are *IL10R* mutations. The main mechanisms related to monogenic IBD include intestinal epithelial barrier function, phagocytic bactericidal activity, hyper- or autoimmune inflammatory pathways, and the development and function of the adaptive immune system (Kelsen et al., 2020). The relationship between PIDs and IBD-like disease is not completely known. Variants of the *MSN* gene have not been reported to be associated with intestinal colitis. Here, we report a VEOBD patient with a novel variant of the X-linked *MSN* gene.

CASE DESCRIPTION

A boy aged 5 years and 2 months presented with recurrent high fever for 18 days, accompanied by a mild cough, abdominal pain, diarrhea and hematochezia. Although he was actively treated with intravenous antibiotics and immunoglobulin, his fever was persistent. He was the first child in his family. A single episode of mild pneumonia had occurred when he was 4 months old and he received intravenous antibiotics for several days. There was no history of recurrent respiratory infection or eczema. No history of prolonged umbilical stump as well. He did not have chickenpox and was not vaccinated against this. On physical examination, he had moderate malnutrition, multiple ulcers in the oral cavity and on the surface of the tongue, and no lymphadenopathy or hepatosplenomegaly. Laboratory examinations revealed obvious elevation of inflammatory markers; the white blood cell count was $19.44 \times 10^9/L$, of which neutrophils accounted for 66.4%; the C-reactive protein (CRP) level was 17.34 mg/L; the erythrocyte sedimentation rate (ESR) was 73 mm/h; and the serum procalcitonin level was 0.412 ng/ml. In addition, the patient had moderate anemia, with a hemoglobin level of 84 g/L, and his serum albumin level was decreased, at 27.4 g/L. Serum antibodies against cytomegalovirus (CMV) and Epstein-Barr virus (EBV) were negative, and a T-SPOT TB test was negative. Number of CD19⁺ B lymphocytes was reduced, accounting for 16.45% (reference range (r.r): 18.5–28.0%) of lymphocytes; CD3⁺ T lymphocytes accounted for 54.1% (r.r: 56.0–68.0%) of lymphocytes, CD4⁺ T lymphocytes accounted for 31.45% (r.r: 29.0–40.0%), and CD8⁺ T lymphocytes accounted for 18.35% (r.r: 19.0–25.0%). The ratio of CD4⁺ to CD8⁺ T cells was normal, 1.71 (r.r: 1.1–2.0/1). Abdominal computed tomography scan showed irregular wall thickness, enhancement of the ascending colon

and terminal ileum wall, and enlargement of the abdominal lymph nodes (**Figure 1A**). Intestinal ultrasound showed that the walls of the terminal ileum and colon were thickened. The inflammation affected the vermiform appendix. Colonoscopy was performed, and multiple ulcers in the terminal ileum and colon were detected. The area of the largest ulcer was approximately 3 cm × 4 cm. The ulcers had sharp margins, and most had no exudate or edema; these lesions were mainly located in the ascending colon and cecum. There were also scattered ulcers located in the rectum (**Figure 1B**). Histological study of a mucosal biopsy indicated segmental chronic active inflammation of the colon and terminal ileum, cryptitis and crypt abscess were observed at the colon; additionally, several noncaseating granulomas was observed in the ileum and descending colon (**Figure 1C**). Microbial metagenomic next-generation sequencing (mNGS) of the intestinal biopsy did not reveal any opportunistic pathogens. The patient was diagnosed with VEOBD and was treated with 2 mg/kg intravenous methylprednisolone twice a day. His fever subsided on the second day of the intravenous methylprednisolone regimen. Then, he was switched to oral prednisone, which was gradually tapered down within 3 months. Repeated colonoscopy showed that the intestinal inflammation was remarkably improved. Only small ulcers in the terminal ileum were observed, and the ulcers located in the colon had healed, leaving a scattering of small inflammatory polyps (**Figure 1D**). Capsule endoscopy confirmed terminal ileal ulcers. The patient took oral mercaptopurine for 4 months. Although he had a wild-type genotype for thiopurine methyltransferase (*TPMT*) and *NUDT15*, he experienced recurrent neutropenia. He was switched to methotrexate (MTX) due to neutropenia, and he had severe sepsis when he was on MTX. He presented with high fever, chill, delirium and shock, accompanied with remarkably elevated CRP and procalcitonin levels. He was treated with vasoactive drug and intravenous antibiotics in the intensive care unit for 1 week. Because of nonspecific intestinal colitis and early onset of disease, he was suspected to have monogenic IBD. The repeated immune work of the peripheral blood was showed in **Supplementary Table S1**. The number and percentage of memory B cells, central CD8⁺ T cells, Th1 cells and NK cells were obviously reduced.

GENETIC ANALYSIS

The patient and his family underwent whole exome sequencing (WES) and trio analysis due to the early onset of intestinal disease. Peripheral blood samples from the patient and his parents were collected and subjected to next-generation sequencing (NGS) at Running Gene Inc. (Beijing, China). In brief, DNA was isolated from peripheral blood using a DNA Isolation Kit (Blood DNA Kit V2, CW2553). For all samples, shearing worked very consistently, and the peak of the size distribution was approximately 200 bp. DNA libraries were prepared with a KAPA Library Preparation Kit (Kapa Biosystems, KR0453) following the manufacturer's

instructions. The libraries were estimated with a Qubit dsDNA HS Assay kit (Invitrogen, Q32851). Array capture, hybridization of pooled libraries to the capture probes and removal of nonhybridized library molecules were carried out according to the SeqCap hybrid mix system. Sequencing, sample dilution, flow cell loading and sequencing were performed according to the Illumina specifications. DNA libraries were sequenced on the Illumina Nova Seq platform as paired-end 200-bp reads. Variant calling and annotation quality control were applied to raw data (stored in FASTQ format) obtained from NovaSeq to guarantee the meaningfulness of downstream analysis. High-quality paired-end reads were aligned to the human reference genome sequence from the UCSC database (build 37.1 version hg19, <http://genome.ucsc.edu/>) using the Burrows–Wheeler Aligner (<https://github.com/lh3/bwa>). We estimated quality scores and performed consensus SNP and insertion and deletion (indel) calling using the Genome Analysis Tool Kit. All the called variants were annotated using several public databases (1000 Genomes Project, ExAC, gnomAD, ESP6500, CCDS, RefSeq, Ensembl, etc.). Candidate variants were classified according to the

American College of Medical Genetics and Genomics (ACMG) guidelines (Richards et al., 2015).

A novel hemizygous mutation, c.934G>T (p. Glu312Ter), was identified in the *MSN* gene. The pathogenic variant in the proband was inherited from his mother (Figures 1E,F). The variant meets PVS1 and PM2, and therefore was likely pathogenic according to ACMG guideline. This pathogenic variant was located in the coiled coil domain of the *MSN*. It was a truncation mutation that resulted in the pre-termination of *MSN* protein. We specially screened variants that associated with IBD as well as PID, and we did not discover any suspected variant. We hypothesize that this pathogenic variant affects the anchor of the *MSN* protein and prevents it from playing its role in regulating the actin cytoskeleton in the relevant cells.

DISCUSSION

Variants in the *MSN* gene were recently reported as the cause of a primary immunodeficiency disease called X-MAID by Chantal Lagresle-Peyrou *et al.* in 2016 (Lagresle-Peyrou et al., 2016). They

TABLE 1 | The clinical and genetic mutation features of those reported in literatures along with our case.

	Gene mutation	Mutation derived	Age of VZV infection, years	Age of evaluation, years	Other infections	Skin manifestations and others	Treatment

VZV, varicella-zoster virus; TTP, thrombotic thrombocytopenic purpura; IVIG, intravenous immunoglobulin; SMZ, sulfamethoxazole; G-CSF, granulocyte-colony stimulating factor; HSCT, hematopoietic stem cell transplantation; CMV, cytomegalovirus; IFX, infliximab.

investigated 7 male patients from 5 different families who had recurrent bacterial and viral infections, especially varicella-zoster virus (VZV) infections (Lagresle-Peyrou et al., 2016). Subsequently, Ottavia M. Delmonte reported a severe combined immunodeficiency patient who was identified by newborn screening and whose MSN mutation was sequenced by WES at 25 months of age (Delmonte et al., 2017). In a 24-year-old man with confirmed immunodeficiency of unknown cause, Gabrielle Bradshaw identified a variant of MSN by WES and whole-genome microarray copy number variant (CNV) analysis (Bradshaw et al., 2018). HUI Xiao-ying reported a similar case in a Chinese boy in 2017 (Xiao-chuan et al., 2017). Sarah E. Henrickson et al. (2019) reported three cases of X-MAID who were presented with severe combined immunodeficiency (SCID) and treatment with HSCT. The laboratory features of X-MAID are reduced lymphocytes, low immunoglobulin and fluctuating neutropenia (Lagresle-Peyrou et al., 2016). There have been only five articles on this disease worldwide, describing a total of 12 patients from nine families; furthermore, there is a ESID registry study calling for an international, multicenter, retrospective study of patients with X-MAID, and they have

collected about a total of 16 patients. Here, we summarized the clinical and genetic mutation features of reported X-MAID patients along with those of our case in **Table 1**. All the patients were male, and the age of genetic diagnosis ranged from newborn to 69 years, with median age of 5 years. The clinical manifestations were recurrent bacterial and viral infections of the respiratory and gastrointestinal systems. Eight patients had skin manifestations, mainly including eczema and molluscum contagiosum. Common immune-associated laboratory features of reported X-MAID are summarized in **Table 2**, including low neutrocyte levels (11/13), low levels of lymphocytes (12/13), reduced CD19⁺ B lymphocytes (13/13), reduced CD4⁺ (13/13) and CD8⁺ T cell counts (12/13), and low levels of IgG (8/10). While our patient presented a different phenotype. He did not have obvious recurrent infections till now, and the predominant clinical feature was IBD-like intestinal inflammatory.

Although MSN mutation affected both T cell and B cell function, patients with X-MAID presented with deficiencies in cellular immunity and humoral immunity. These patients had a relatively good prognosis. The oldest patient was 69 years old, and the most severe condition was severe pneumonia accompanied by

shock. Other complications were common infections and were treated with immunoglobulin infusion and antibiotics. Sulfamethoxazole (SMZ) tablets and recombinant human granulocyte colony-stimulating factor (G-CSF) were used to prevent opportunistic infections for recurrent neutropenia. Three patients exhibited severe combined immunodeficiency received hematopoietic stem cell transplantation (HSCT). However, mutations in the *MSN* gene that can lead to IBD-like feature have not been reported, and the optimal treatment of colitis caused by *MSN* variant is not clear. Remission of inflammatory colitis was induced with steroid and maintained with anti-TNF therapy in this case. There is no standard treatment for VEOIBD or IBD-like features caused by immunodeficiencies, the main treatment included supporting treatment, symptomatic treatment and conventional treatment for IBD, such as steroids, immunosuppressants, biological treatment and thalidomide, et al. The patient in our case had persistent fever, no chronic history of disease, and the endoscopy and pathological finding of biopsy indicated the feature of IBD, so we used steroid to induce remission. The patient did not have allergy history, and his nutrition status was normal, so he did not have any special diet.

The human moesin gene, *MSN*, is located on chromosome Xq12 and has 13 exons distributed over more than 30 kb. Only two different variants of the *MSN* gene have been reported. Eleven patients were identified to harbor the same variant of c.511C>T (p. Arg171Trp), which is located in the FERM domain. Another reported variant is c.1657C>T (p.Arg553Ter), which is located in the F-actin binding domain. Our case has a nonsense variant of c.934G>T (p.Glu312Ter) located in the coiled coil domain. This variant alters the codon for Glu312 to a termination codon, which causes premature termination of *MSN* protein synthesis. Our case is the second reported nonsense variant in *MSN* gene, and the phenotype is differed from other pathogenic variants, which may suggest that nonsense variants in *MSN* may cause IBD-like features. The variant of c.934G>T (p.Glu312Ter) is classified as

a variant of likely pathogenic according to the ACMG guidelines (Richards et al., 2015). The pLi score for *MSN* in gnomAD is 1, which means the gene is highly intolerant of loss of function variants (Ziegler et al., 2019), this adds further evidence that *MSN* variants cause immunodeficiency and widen the reported phenotypes.

MSN protein is mainly expressed in endothelial cells, lymphocytes and platelets, and it regulates the actin cytoskeleton. *MSN* knockout mice was observed to impair the migration and adhesion of lymphocyte cells; naive CD8⁺ T cells were affected most. Recently, isolated CD8⁺ Treg cells from moesin-deficient mice exhibited impaired proliferation in response to IL-15, which shows the importance of moesin in IL-15-dependent CD8⁺ Treg cell homeostasis (Satooka et al., 2017). Additionally, moesin regulates NK cell survival through IL-15-mediated signaling *in vivo* (Satooka et al., 2021). Altogether, *MSN* mutation may affect both innate and adaptive immunity *in vivo*. However, the underlying mechanism by which variants of *MSN* causes IBD-like features needs further investigation.

PIDs have a cross-connection with VEOIBD. The actin cytoskeleton is required for many immune cell functions, including migration, adhesion, phagocytosis, assembly of complex intercellular contacts, and cell division (Burns et al., 2017). PID-associated actin regulatory defects include Wiskott-Aldrich syndrome (WAS), WASp-interacting protein (WIP) deficiency, *DOCK2* and *DOCK8* deficiencies, moesin deficiency, leukocyte adhesion defects (LAD1, 2, 3 and IV) and megakaryoblastic leukemia 1 (*MKL1*), and these defects lead to combined immunodeficiencies or phagocyte disorders (Burns et al., 2017). It has been reported that WAS can present as IBD-like intestinal inflammation (Ohya et al., 2017). We suspect that the mechanism of *MSN*-associated colitis is as follows. First, similar to WAS, *MSN* is a member of the cell-structure-related proteins that regulates the cell actin cytoskeleton and plasma membrane. The actin cytoskeleton is required for many immune cell functions. Dysfunction of immune cells is related to nonspecific colitis or IBD-like features. Secondly,

MSN is dominantly expressed on lymphocytes, which plays an important role in the regulation of intestinal inflammation. Chronic intestinal inflammation could lead to IBD-like features. In our case, the boy exhibited severe intestinal inflammation at first, a decrease in B lymphocytes and neutrocytes, low albumin, and elevation of CRP and ESR, and he was not responsive to intravenous antibiotics treatment. The negative result of blood serologic tests, immunohistochemistry study and the mNGS test of the mucosal biopsy did not indicate any infection that caused the inflammation of the colon. The WES did not reveal any causative variant that related to PID or VEOIBD. After the administration of steroid, the inflammatory markers and intestinal inflammation were obviously improved, which indicated that an immune mechanism participated in the process of inflammation. However, other typical phenotypes of X-MAID patients, such as hypogammaglobulinemia, neutropenia, VAZ infection, recurrent respiratory tract infections, and eczema, were not obvious in this patient. The mechanism of intestinal inflammation in this patient is not clear, but we presume that it may be associated with dysregulation of immune cells and altered functioning of lymphocytes. Intriguingly, some immunocompromising diseases, such as common variable immunodeficiency, hyper-IgM syndrome, and selective IgA deficiency, present with IBD-like intestinal inflammation (Albshesh et al., 2021). In an immunocompromised patient, opportunistic infections, such as cytomegalovirus or Epstein-Barr virus infection, may contribute to intestinal inflammation as well. However, this patient did not have recurrent infections, and his pathogen tests were negative. The mNGS of an intestinal biopsy was negative as well. The patient's colon ulcers were almost completely healed after steroid treatment, which may indicate that the ulcers were induced by immune dysregulation. He could not tolerate mercaptopurine or MTX, so he was ultimately switched to IFX to induce and maintain mucosal healing. The intestinal ulcers were healed after three doses of infused IFX.

In conclusion, we reported a patient with nonsense variant of MSN who presented with IBD-like features. This is the first reported case of an X-MAID patient mainly presented with enteropathy. The pathogenesis of intestinal colitis is not clear and requires further basic medical research.

Background: Psoriasis vulgaris is an inflammatory skin disease. Observational studies have shown associations between circulating cytokine levels and psoriasis vulgaris. But the causal relationship between circulating cytokine and psoriasis vulgaris remains elusive.

Methods: To assess the causal effects of cytokine levels on the risk of psoriasis vulgaris and vice versa, we performed a two-sample Mendelian randomization (MR) study by using the inverse-variance weighted (IVW), weighted median, and Mendelian randomization pleiotropy residual sum and outlier (MR-PRESSO) in genome-wide association summary statistics of 41 circulating cytokines in up to 8,293 individuals and psoriasis vulgaris in 399,883 individuals.

Results: We identified that increasing RANTES level induced an elevated risk of psoriasis vulgaris in IVW ($\beta = 0.33$, S.E. = 0.12, $p = 0.006$). This causal effect showed consistency across the weighted median ($\beta = 0.35$, S.E. = 0.15, $p = 0.022$) and MR-PRESSO method ($\beta = 0.33$, S.E. = 0.11, $p = 0.028$).

Conclusions: Our results suggest a potential causal effect of elevated RANTES concentration on the increased risk of psoriasis vulgaris.

Keywords: psoriasis vulgaris, cytokines, causal effect, mendelian randomization, RANTES

INTRODUCTION

Psoriasis vulgaris is a chronic inflammatory skin disease, affecting about 2% of the population around the world (von Csiky-Sessoms and Lebwohl, 2019; Rendon and Schäkel, 2019). The prevalence of psoriasis vulgaris varies across regions, ranging from 0.05 to 0.47% in Asia to 2–3% in Europe and the United States (Hawkes et al., 2017; Kaufman and Alexis, 2018). It is clinically characterized by erythema lesions covered with pearly scales (Hawkes et al., 2017; Rendon and Schäkel, 2019). The exact cause of psoriasis vulgaris is not well understood. Observational studies have shown associations between psoriasis vulgaris and circulating cytokines such as IL-23, IL-17 and TNF- α (de Alcantara et al., 2021). However, the causal relationship between cytokines and psoriasis vulgaris remain unresolved.

Since observational studies are susceptible to reverse causality and confounding factors, it is unable to provide convincing evidence for causality alone (Smith and Ebrahim, 2004). For instance, elevated IL-22 levels have been observed in both skin lesions and blood, the strategy of blocking IL-22

in the treatment of psoriasis failed in a clinical trial (Chiricozzi et al., 2018). Studies show that plasmacytoid dendritic cells in psoriatic lesions produce IFN- α , suggesting a key role of IFN- α in the pathogenesis of psoriasis (Gilliet et al., 2004; Nestle et al., 2005). However, a randomized trial failed to provide evidence that targeting IFN- α improved clinical symptoms in patients with plaque psoriasis (Bissonnette et al., 2010). Many studies detect an increasing level of IL-17 in the occurrence and development of psoriasis (Harper et al., 2009; Johansen et al., 2009; Ramirez-Carrozzi et al., 2011). But in an experimental study, IL-17 restored the function of keratinocytes and played a protective role in the development of psoriasis (Kanda et al., 2005; Deng et al., 2016).

Mendelian randomization (MR) uses genetic variation that are strongly associated with a possible exposure as instrumental variables (IVs) to assess the causality of the given exposure on an outcome of interest (Emdin, et al., 2017). Compared with observational studies, MR is immune from reverse causality and confounding factors. In past decade, genome-wide association studies (GWAS) have identified tens of thousands of genetic variants robustly associated with complex traits (Hemani, et al., 2018). These findings reveal the genetic underpinning of complex traits. The associated genetic variant can be used as IVs and facilitate the application of MR to identify disease's causal factors (Davey Smith and Hemani, 2014).

To better understand the causal role of cytokines in the development of psoriasis vulgaris and to search for disease prevention and treatment targets of potential, we performed a two-sample MR to evaluate the causal relationship between circulating cytokines concentrations and the risk of psoriasis vulgaris. We identified single nucleotide polymorphisms (SNPs) from GWAS meta-analysis for 41 circulating cytokines in 8,293 Finns as IVs. We evaluated the causal effect of circulating cytokines on psoriasis vulgaris with SNPs which were identified, and the genome-wide association statistics for psoriasis vulgaris in the United Kingdom biobank. Our study suggests a potential causal association between circulating RANTES levels and the risk of psoriasis vulgaris. This finding helps identify a potential target for the intervention of psoriasis.

MATERIALS AND METHODS

Genome-Wide Association Summary Statistics

We accessed genome-wide association summary-level statistics for 41 circulating cytokines and psoriasis vulgaris. In brief, the summary-level data for 41 cytokines included ~ 10.7 million SNPs and 8,293 Finnish individuals from the Cardiovascular Risk in Young Finns study, FINRISK 1997, and FINRISK 2002 (Ahola-Olli et al., 2017). The cytokine levels were quantified by Bio-Rad's premixed Bio-Plex Pro Human Cytokine 27-plex Assay and 21-plex Assay, and Bio-Plex 200 reader with Bio-Plex 6.0 software. Genotype imputation inference was based on reference haplotypes from the 1000 Genomes Project Phase 1 (1000 Genomes Project Consortium et al., 2010). The single-variant association was accomplished through a linear regression

between cytokine levels and SNPs after adjusting for age, sex, and body mass index (Ahola-Olli et al., 2017).

We used genome-wide association statistics for psoriasis vulgaris in the United Kingdom biobank (Sudlow et al., 2015). The United Kingdom Biobank defined psoriasis vulgaris using International Classification of Diseases (ICD) L40.0 based on the medical records and questionnaire data for each participant. The United Kingdom biobank data contains 1,684 psoriasis vulgaris cases and 398,199 controls of White British. GWAS was accomplished between the risk of psoriasis vulgaris and 31.3 million SNPs through SAIGE (Sudlow et al., 2015; Zhou et al., 2018). About 8.4 million SNPs were overlapped with the GWAS for circulating cytokines. No ethical approval was required.

Identification of IVs

The IVs for MR have three assumptions: 1) IVs must be strongly associated with exposure. 2) IVs are not associated with any known confounders related to outcome or exposure. 3) IVs cannot affect the outcome in other ways except through exposure (Lawlor et al., 2008). To identify IVs for MR analysis, we performed linkage disequilibrium (LD) pruning in Plink 2.0 in the 8.4 million overlapping SNPs at $P < 1 \times 10^{-6}$ in cytokine GWAS summary statistics using LD $r^2 < 0.1$ in distance ≥ 500 kilobases (kb) (Machiela and Chanock, 2015; Sobota et al., 2015). After screening, 420 SNPs associated with 40 cytokines were used for further analyses as IVs. To attain a stable assessment, we restricted our MR analyses to 35 of the 41 cytokines with the number of IVs ≥ 3 .

MR Analysis

To test the potential causal effects of circulating cytokine levels on the risk of psoriasis vulgaris and vice versa, we ran MR analysis by using three two-sample MR methods: IVW, weighted median, and MR-PRESSO (Burgess et al., 2017; Verbanck et al., 2018). These three methods make different assumptions and deal with the potential horizontal pleiotropy differently. The IVW method integrates causal effects assessment from multiple genetic variants, assuming that all IVs are valid and free of interference from heterogeneity and pleiotropy (Pierce and Burgess, 2013). When at least 50% SNPs are valid instruments, weighted median test is recommended (Bowden et al., 2016). The MR-PRESSO test is appropriate when less than 50% of the genetic variants have a pleiotropic effect (Verbanck et al., 2018). We required the causal effects consistent across all the three methods and used a significance threshold $p < 0.05$ to define a significant causal effect (Burgess et al., 2017; Verbanck et al., 2018).

Test for Heterogeneity and Pleiotropy

To evaluate the validity of the MR core hypothesis, we performed a series of assessments of heterogeneity and pleiotropy. MR-PRESSO method can test the directional pleiotropy and identify and correct potential outliers (Verbanck et al., 2018). We evaluated horizontal pleiotropy by examining the intercept term of MR Egger's regression (Bowden et al., 2015). If the intercept term is significantly different from zero at $p < 0.05$, horizontal pleiotropy exists (Bowden et al., 2015). We calculated a Cochran's Q-statistic to quantify the heterogeneity of causal effects across all IVs (Egger et al., 1997).

TABLE 1 | MR analysis of the causal relationship between RANTES, SDF-1 α , MIP-1 β and IL-17 levels and psoriasis vulgaris.

Cytokines	No. of SNPs	Association			Heterogeneity	MR-PRESSO global Test
		β	S.E.	P-Value	P-Value	P-Value
RANTES						
IVW	6	0.325	0.119	0.006	0.55	—
Weighted median	6	0.348	0.153	0.022	—	—
MR-PRESSO	6	0.325	0.106	0.028	—	0.617
SDF-1 α

Note: Significant results are shown in bold.

RESULTS

Selection of IVs

For 35 of the 41 cytokines, we identified at least three genetic variants available at $p < 1 \times 10^{-6}$ and LD ($r^2 < 0.1$, distance ≥ 500 kb). The numbers of IVs for each cytokine are shown in **Table 1**. The associations of IVs with each circulating cytokine level can be found in **Supplementary Table S1**.

Causal Effects of Cytokine Levels on the Risk of Psoriasis Vulgaris

Among the 35 cytokines, genetically predicted RANTES, SDF-1 α , MIP-1 β and IL-17 were associated with the risk of psoriasis vulgaris in at least 1 MR method at the significance threshold ($p < 0.05$; **Table 1**). MR results of the rest 31 cytokines in our analyses can be found in **Supplementary Table S2**. In the four cytokines RANTES, SDF-1 α , MIP-1 β , and IL-17, only the causal effect of RANTES on psoriasis vulgaris was significant in all the 3 MR methods: IVW ($\beta = 0.325$, S.E. = 0.119, $p = 0.006$), weighted median ($\beta = 0.348$, S.E. = 0.153, $p = 0.022$), and MR-PRESSO ($\beta =$

0.325, S.E. = 0.106, $p = 0.028$; **Table 1** and **Figures 1, 2**). We identified six IVs for the MR analysis evaluating the causal effect of RANTES. The causal effects of these six IVs on the risk of psoriasis vulgaris showed no statistically significant heterogeneity (Cochran's Q-test $p = 0.55$; **Table 1**). We observed no evidence of horizontal pleiotropy in the MR-PRESSO (Global test $p = 0.62$; **Table 1**) or the MR-Egger regression (p for intercept = 0.69; **Supplementary Table S3**).

Causal Effects of Psoriasis Vulgaris on Circulating Cytokine Levels

Reversely, we identified causal effects of the onset of psoriasis vulgaris on 11 circulating cytokine levels including IL-1ra, IL-5, CTACK, MIG, VEGF, IL-8, IL-9, IL-13, IL-12p70, TNF- α , and IL-2 at $p < 0.05$ in at least one of the 3 MR methods based on MR results from **Supplementary Table S4**. Out of these 11 cytokines, the causal effects of psoriasis vulgaris achieved consistently significant on IL-1ra, IL-5, and MIG in all the 3 MR methods. We did not detect significant heterogeneity of causal effects (Cochran's Q-test $p > 0.05$; **Supplementary Table S4**) or horizontal pleiotropy (MR-PRESSO Global test $p > 0.05$ and MR Egger's regression intercept $p > 0.05$; **Supplementary Tables S4, S5**).

DISCUSSION

Studies have shown significant associations between circulating cytokines and psoriasis vulgaris, but the causal relationship between cytokines and psoriasis vulgaris remain unclear. In our study, we leveraged large-scale GWAS for 41 circulating cytokines and psoriasis vulgaris and evaluated the causal relationship between circulating cytokines and psoriasis vulgaris by using three two-sample MR approaches. We identified a causal effect of elevated RANTES levels on the increased risk of psoriasis vulgaris. We also assessed the causal effects of psoriasis vulgaris risk on circulating cytokine concentrations, which found that increased risk of psoriasis vulgaris resulted in elevated circulating levels of IL-1ra, IL-5, and MIG.

Psoriasis vulgaris is characterized by abnormal epidermal hyperplasia and differentiation, with accumulation and infiltration of neutrophils and pro-inflammatory T cells in the *epidermis* and *dermis* (Chiricozzi et al., 2018). RANTES is a pro-inflammatory chemokine, which not only mediates the infiltration of lymphocytes, granulocytes, natural killer cells, and dendritic cells into the inflammatory lesions, but also activates leukocytes to play a role in the inflammatory response (Appay and Rowland-Jones, 2001; Levy, 2009; Marques et al., 2013). RANTES has been reported to play an important role in leukocyte recruitment to psoriatic skin lesions (Nedoszytko et al., 2014; Zabltona et al., 2016). Studies have shown that RANTES production increased in psoriatic lesions compared with non-lesion skin, and was mainly present in keratinocytes or the intercellular space between keratinocytes in psoriatic lesions, from the middle to the marginal lesions of

psoriatic plaques (Rateb et al., 2012; Johansen et al., 2017; Joshi et al., 2019). The expression of RANTES's receptor CCR5 was enhanced in epidermal T cells, and the number of CCR5 positive cells raised significantly too (de Groot et al., 2007; Joshi et al., 2019). Phototherapy has been reported to inhibit the production of RANTES in patients with psoriasis. After treatment with NB-UVB, the expression of RANTES was significantly reduced (Rateb et al., 2012; Joshi et al., 2019). According to several case-control trials, serum concentrations of RANTES were significantly higher in patients with psoriasis compared with healthy controls (Rateb et al., 2012; Duarte et al., 2015; Zabltona et al., 2016). However, in a recent case-control study from northern India, serum RANTES levels were significantly reduced in 40 patients with chronic plaque psoriasis compared with 25 healthy controls (Joshi et al., 2019). Previous studies on the relationship between RANTES and psoriasis were observational, difficult to exclude potential confounding factors, and the sample size was small. In this study, we performed a two-sample MR using large sample size GWAS data and found that high RANTES expression was associated with increased risk of psoriasis vulgaris, indicating the positive role of the genetically predicted RANTES for psoriasis vulgaris risk.

We consistently found that psoriasis vulgaris affects the circulating levels of IL-1ra, IL-5, and MIG, which are consistent with previous findings. Abundant IL-1ra expression was found in psoriatic lesions (Hammerberg et al., 1992). IL-1ra expression was elevated in peripheral blood mononuclear cells of psoriasis patients compared with controls (Kim et al., 2016), while serum IL-5 levels were significantly elevated in psoriatic patients and were significantly overexpressed during the active phase of psoriasis vulgaris (Dong et al., 2021). MIG is induced by IFN- γ and can induce T cells by chemotaxis (Duarte et al., 2015). Studies showed that MIG was highly expressed in psoriatic patients and mediated T cell aggregation and activation (Goebeler et al., 1998; Duarte et al., 2015).

Compared with traditional observational studies, our MR study overcomes the bias caused by confounding and reverse causality issues and provides more reliable evidence for assessing the causal relationship between circulating cytokine concentrations and the risk of psoriasis vulgaris. However, there are some limitations in our MR study, which may influence the causal inference between cytokines and psoriasis vulgaris. Firstly, the sample size of the cytokine GWAS was limited, limiting the statistical power of causal assessment in MR. This may explain IL-17, IL-23, and TNF- α whose biologics are effective for treating psoriasis but did not yield statistically significant results in our MR analysis. Secondly, we used the significance p -value threshold at 1×10^{-6} instead of 5×10^{-8} . The lenient P -value threshold increased the number of available IVs for MR but might cause weak IV bias. Thirdly, our MR study could only demonstrate the lifetime effects of higher cytokines on psoriasis vulgaris, and the effect of short-term regulation of cytokines, such as biological agents targeting cytokines, on psoriasis vulgaris is difficult to assess. Therefore, in the future studies, we need to further explore the biological functions of

cytokines to better understand the relationship between cytokines and psoriasis vulgaris.

CONCLUSION

We identified a causal effect of circulating RANTES levels on the risk of psoriasis vulgaris. This finding might help explore the mechanisms of RANTES in the pathogenesis and development of psoriasis and guide the evaluating of RANTES as a potential intervention target for psoriasis vulgaris.

DATA AVAILABILITY STATEMENT

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found in the article/**Supplementary Material**.

AUTHOR CONTRIBUTIONS

PZ oversaw the conception of the study, design, as well as the collection, analysis and interpretation of data, and drew up the

manuscript. JZ and BL were involved in the design of the research. YT, LW, and GW undertook some data analysis and interpretation work. HW, CY, XL, and BL contributed to data collection and interpretation.

FUNDING

Our research work was supported by Anhui Provincial Natural Science Foundation (2008085MH261), and Science Foundation of Anhui Medical University (2021xkj119).

We aimed to explore the genotypic and phenotypic characteristics of neonatal-onset inflammatory bowel disease (IBD) with combined immunodeficiency due to *TTC7A* mutation. We examined the clinical manifestations, imaging results, endoscopic and histological findings, interventions, and prognosis of a proband with neonatal-onset IBD and performed biochemical analyses, whole-exome sequencing (WES), and *in silico* analysis. Our proband developed severe early-onset diarrhea, malnutrition, electrolyte imbalance, dehydration, and recurrent infections after birth. Radiographic and ultrasonic images showed no specific manifestations. Endoscopic and histological examination revealed chronic inflammation. Immune function examination indicated immunodeficiency. WES identified compound heterozygous *TTC7A* mutations (c.2355+4A>G, c.643G>T) in the proband. In the expression analysis, no abnormal splicing in the *TTC7A* sequence was observed due to the c.2355+4A>G mutation; however, the mRNA expression was reduced. The proband's condition did not improve after treatment with methylprednisolone or leflunomide. The proband died when treatment was stopped at the age of 5 months and 19 days. Compound heterozygous mutations (c.2355+4A>G, c.643G>T) in the *TTC7A* gene are described and verified for the first time. Our report expands the phenotypic spectrum of *TTC7A* mutations and the genotypic spectrum of very early-onset IBD with combined immunodeficiency.

Keywords: inflammatory bowel disease, immunodeficiency, neonatal, *TTC7A*, intervention

INTRODUCTION

Very early onset inflammatory bowel disease (VEOIBD) encompasses a group of diseases in children aged less than 6 years (Kelsen et al., 2019); it has a unique clinical presentation with severe colonic disease in infancy (Griffiths, 2004; Muise et al., 2012a). Mutations in *IL10RA/B*, *IL106*, *XIAP7*, *ADAM178*, *NCF49*, *NCF2/RAC210*, and *TTC7A* cause a severe form of VEOIBD, with symptoms developing in infancy (Glocker et al., 2009; Matute et al., 2009; Glocker et al., 2010; Blaydon et al., 2011; Worthey et al., 2011; Muise et al., 2012b; Kelsen and Sullivan, 2017). *TTC7A*, a member of the tetratricopeptide repeat (TPR) domain-containing proteins, has multiple functions in cell cycle control, phosphate turnover, and protein transport and secretion (White et al., 2005). *TTC7A* gene mutations occur in several patients with multiple intestinal atresia (MIA) and gastrointestinal defects, immunodeficiency syndrome, and inflammatory bowel disease (IBD) with or without immunodeficiency; they are inherited in an autosomal recessive manner (OMIM: 609332). Approximately 50 cases of *TTC7A* deficiency have been reported worldwide, most of which are MIA with combined immunodeficiency (CID), and only a few are IBD cases (Jardine et al., 2019a). Missense *TTC7A* mutations often result in clinical features of VEOIBD, and truncating *TTC7A* mutations (nonsense, frameshifts, or large deletions) are associated with greater morbidity and mortality in MIA-CID patients (Samuels et al., 2013; Avitzur et al., 2014; Bigorgne et al., 2014). Patients with mutations affecting the splice acceptor sites present with intestinal atresia, increased intestinal cell apoptosis, and severe bowel inflammation (Samuels et al., 2013); however, it is difficult to establish a significant correlation between the genotype and phenotype. Most patients were diagnosed within 1 year after birth; only two patients were diagnosed in the neonatal period (Jardine et al., 2019a). Neonatal-onset IBD often exhibits a poor response to conventional treatments in contrast to adult-onset IBD (Heyman et al., 2005).

In this study, we describe the clinical presentation, imaging results, pathological features, functional analysis, treatment, and prognosis of a proband with neonatal-onset IBD caused by two novel *TTC7A* compound heterozygous mutations. There was no improvement in the proband's condition after treatment with methylprednisolone or leflunomide. This is the first known case of *TTC7A* mutations in mainland China and it extends the pathogenic spectrum of this gene.

MATERIALS AND METHODS

Proband

We retrospectively studied a proband from the Women and Children's Hospital, School of Medicine, Xiamen University, China. All relevant clinical information was collected, including clinical progression, laboratory findings, imaging, and endoscopic and histological characteristics. Stool electrolytes were detected using biochemical testing methods.

TABLE 1 | Lymphocyte subsets and immunoglobulin levels of the proband.

Whole-Exome Sequencing and Variant Classification

Peripheral blood samples of the proband, his parents, and control (a normal peer) were collected, and trio-based WES was performed at Guangzhou KingMed Diagnostics Group Co. Ltd. (Guangzhou, China). Genomic DNA was extracted using the QIAamp DNA Mini Kit (Qiagen, Hilden, Germany), and mechanical shearing was performed using Covaris AFA-energetics® (Covaris Inc., Woburn, MA, United States) according to the manufacturer's instructions. DNA library preparation and adaptor hybridization were performed according to the standard procedures of the Agencourt AMPure XP Beads (Beckman Coulter Inc., Brea, CA, United States). The DNA library was used to capture and collect DNA from the target exons and adjacent splice sites, using the Agilent SureSelect Human All Exon V6 kit (58 M). Finally, PE150 + 150 sequencing was performed using Illumina NovaSeq 6000 platform (Illumina, Inc., San Diego, CA, United States). The reads were mapped to the reference human genome (UCSC hg19).

Primers were designed to amplify the candidate regions of the mutations identified using WES. Subsequently, Sanger sequencing using ABI PRISM 3130XL gene analyzer (Applied Biosystems, California, United States) was performed.

In Silico Analysis

All variants were compared with the data in the 1000 Genomes Project (<https://www.internationalgenome.org>), Exome Aggregation Consortium (ExAC) (<https://exac.broadinstitute.org/>), and dbSNP (<https://www.ncbi.nlm.nih.gov/snp/>) databases. Variants with greater than 0.01 minor allele frequency in the control databases were excluded. Pathogenicity predictions for proteins were performed using Revel, SIFT, PolyPhen2, PROVEAN_pred, LRT_pred, Mutation Taster, etc.

Analysis of *TTC7A* Expression

Total RNA was extracted from the peripheral blood lymphocyte cell lines using PowerUp™ SYBR Green Master Mix Kit (Life Technologies). The mRNA was reverse transcribed to cDNA using RevertAid First Strand cDNA Synthesis Kit (Thermo

FIGURE 1 | Ultrasonography of the proband's abdomen. Thickening of the small intestine and colon, enhanced echogenicity of the mucous membrane and submucosa, and effusion in the colon are visible (A,B). Low-echogenicity area in the gallbladder (bile sludge) (C) can be seen, which disappeared the next day.

Scientific). The region near the splice site was amplified using the primers, 5'-TCCCCACTTCTCACTCAGTACTC-3' and 5'-GTG GCACGTACTCTGCCTCT-3' (product length: 218 bp), followed by agarose gel electrophoresis and sequencing through Sanger sequencing. Real-time quantitative PCR (qPCR) was performed to verify whether the splice site mutation affected the mRNA expression. The relative standard curve method was used to analyze the expression level. The expression was normalized to that of *ACTB* in the same sample; three biological repeats were measured. The real-time PCR primers used were: *TTC7A*, 5'-ATGCATAGCCTGGGT CTGAT-3' and 5'-GTGGCACGTACTCTGCCTCT-3' (product length: 96 bp); *ACTB*, 5'-TGGTGCCAGATTTTC TCCA-3' and 5'-GGCATGGGTCAGAAGGATT-3' (product length: 128 bp).

Informed Consent

Written informed consent for genetic testing and the publication of research data was obtained from the proband's parents. The protocol was approved by the Women and Children's Hospital Ethics Committee (KY-2020-011).

RESULTS

Clinical Features of the Proband

The proband, a male infant conceived *via in vitro* fertilization, was born to non-consanguineous Chinese parents at 35 weeks and 6 days of gestation. The clinical characteristics of his parents were normal; and the mother and father were aged 27 and 29 years, respectively. No complications were observed during the prenatal period. No exposure to toxic or harmful substances during pregnancy was reported. There was no family history of genetic diseases. His birth weight and length were 2,800 g and 50 cm, respectively. He was breastfed after birth and presented with diarrhea with yellow, watery, and bloody stool 5–10 times per day. He was admitted to a tertiary children's hospital; however, he showed no improvement after 1 week of antimicrobial treatment. He was admitted to our hospital for further treatment, at the age of 1 month and 8 days, with a weight of 2,600 g, head circumference of 33 cm, and body length of 50 cm, without dysmorphic features. The proband had

FIGURE 2 | X-ray of the proband's abdomen revealed stiffness in the intestines and low volume of intestinal gas.

malnutrition, moderate dehydration, and severe perianal dermatitis.

Because of the large quantity of watery stool (approximately 300–940 ml/day), total parenteral nutrition, amino acid milk powder, deep hydrolyzed protein milk powder, or breast milk were administered after admission; however, there was no improvement in his condition. The stool was considered to be high-output secretory diarrhea. Severe hypokalemia, hyponatremia, and metabolic acidosis occurred, and the proband recovered after total parenteral nutrition every day. The erythrocyte sedimentation rate was normal; however, the ferritin levels were >1,500 ng/ml (reference value <200 ng/ml). Interleukin (IL)-6 levels reached 74.6 pg/ml (reference value ≤5.9 pg/ml), and the tumor necrosis factor-α level was 39.2 pg/ml (reference value ≤8.1 pg/ml). A diagnosis of IBD was suspected.

During hospitalization, the proband had recurrent fever; blood immune function investigation indicated CID (Table 1). The test for cytomegalovirus antibody in the blood was negative; however, the amounts of cytomegalovirus DNA in the blood and urine were 4.12×10^6 copies/ml and 1.47×10^6 copies/ml, respectively. Cytomegalovirus and *Pneumocystis carinii* were detected in the bronchoalveolar lavage fluid through metagenomic detection; *Candida albicans* was detected in urine culture and sputum culture. The risk factors for these infections include malnutrition, CID, long hospital stays, and long-term use of antibiotics and hormones.

FIGURE 3 | Gastroscopy and colonoscopy of the proband. Mucosal erosion and edema of the pylorus revealed by gastroscopy (A). Colonoscopy revealed the mucosa of the whole colon to be rough; the surface was scattered with a white pseudomembrane. Part of the intestinal mucosa was eroded, and the intestine was slightly narrow (B).

FIGURE 4 | Histopathological findings of the proband's intestine. Chronic mild superficial inflammatory changes are seen in the esophagus and stomach. The duodenal crypt was atrophied, and plasma cells were scattered in the interstitium (A). Twisted colon crypts, mucus hypersecretion (B), focal epithelial hyperplasia, and basal plasmacytosis are evident in the large intestinal mucosa (C).

The proband received cefotaxime, piperacillin-tazobactam, cefoperazone-sulbactam, meropenem, ganciclovir, co-trimoxazole, fluconazole, voriconazole, and intravenous immunoglobulin (IVIG). Methylprednisolone 1–2 mg/kg/day was given intravenously for 11 days. He received leflunomide (the dose increased over time from 0.5 to 1.0 mg/days) for 4 weeks, commencing at the age of 4 months 23 days. Although his infections were under control after comprehensive treatment, he still presented with refractory diarrhea, and his weight remained in the range of 2,300–3,400 g after 4 months. The infant died when his parents discontinued treatment at the age of 5 months and 19 days.

Imaging Features and Endoscopic and Histological Characteristics

The proband underwent abdominal ultrasound, radiography, gastroscopy, colonoscopy, and biopsy pathological analyses (Figures 1–4). Gastroscopy and colonoscopy examination were performed on days 98 and 100, respectively.

WES and Variant Classification

Trio-based WES identified two novel heterozygous variants in *TTC7A*: a mutation in exon 4, c.643G>T, inherited from his

father, and another in exon 19, c.2355+4A>G inherited from his mother. According to the American College of Medical Genetics and Genomics and the Association for Molecular Pathology variant-interpretation guidelines (Richards et al., 2015) and the work groups from ClinGen (<https://clinicalgenome.org/>), the nonsense mutation c. 643G>T causes premature termination of the protein at amino acid 215 (p. Glu215X); the variant is classified as a pathogenic variant (PVS1 + PM2-supporting + PP3). The intronic allele c.2355+4A>G is predicted to affect mRNA splicing of *TTC7A* transcripts, according to dbSNV_ADA and dbSNV_RF; the variant is classified as a variable of uncertain significance (PM2-supporting + PP3; Figure 5).

TTC7A Expression Analysis

No abnormal splicing bands were observed in the agarose gel electrophoresis; no abnormal splicing sequences were detected using Sanger sequencing. However, the expression of *TTC7A* mRNA decreased in the proband ($p < 0.01$), which could have resulted in a decrease in the protein levels. However, no aberrant expression of *TTC7A* was detected in the parents (Figures 6–8). The decrease in mRNA expression could lead to decreased protein expression or the production of the wrong protein (Chen et al., 2013; Bigorgne et al., 2014).

DISCUSSION

The global incidence rate of IBD is 37.5/100,000 annually. In the United States, the incidence of IBD was the highest in adults (18–59 years) and older adults (>60 years) from 2005 to 2015 and the lowest in pediatric patients (0–17 years) (Keyashian et al., 2019). In a study of 1,412 pediatric cases, VEOIBD accounted for approximately 3% of cases, and infantile-onset IBD accounted for only 1%. The incidence of VEOIBD remained stable over the study period (1988–2011); however, the incidence of EOIBD increased (Bequet et al., 2017). These results suggest a probable genetic origin for VEOIBD, whereas the increased incidence in older children may be linked to environmental factors (Bequet et al., 2017). The most important clinical sign of monogenic IBD is the young age at onset. In this study, the case was initially thought to be related to genetic factors because of the very early onset and severe symptoms.

Neonatal or infantile-onset IBD is often associated with primary immune deficiency disorders, especially those caused by mutations in *IL-10*, *XIAP*, *NCF2*, *IPEX*, and *TTC7A* (Kelsen and Sullivan, 2017). *TTC7A* has 20 exons and nine TPR domains, and mutations in exons 2, 7, and 20 are relatively common (Lien et al., 2017). TPR domains are structurally conserved helix-turn-helix motifs that play an important role in protein scaffolding and have large surface areas that accommodate multiple protein

interactions (Blatch and Lässle, 1999; Zeytuni and Zarivach, 2012). No case of *TTC7A* mutation was reported in mainland China, before this case. Our proband had two novel *TTC7A* mutations, c.643G>T in exon 4, inherited from his father, and c.2355+4A>G in exon 19, inherited from his mother, which was not described in the Human Gene Mutation Database. *TTC7A* mutation exhibits an autosomal recessive inheritance pattern; the proband's parents have normal phenotypes. The c.643G>T mutation, a nonsense mutation in exon 9, results in premature termination of the protein and is predicted to cause loss of function. qPCR showed that the c.2355+4A>G mutation decreased *TTC7A* mRNA expression. We believed that this intron mutation would affect splicing; however, the experimental results revealed that this was not the case.

To date, few studies have performed functional analysis of the specific variants of *TTC7A*. We did not perform immunostaining analysis for assessing the proteins; however, we speculate that the c.2355+4A>G mutation could affect the TPR domain, which binds and recruits phosphatidylinositol 4 (PI4)-kinase III alpha to the plasma membrane. This process facilitates the synthesis of mutant PI4-phosphate affecting the TPR domain, resulting in negative phenotypes and poor outcomes (Lien et al., 2017). Studies on truncating *TTC7A* mutations suggested that nonsense-mediated decay of *TTC7A* mRNA transcripts showed an obvious loss of protein, consistent with the increased phenotypic severity in

FIGURE 7 | Gel electrophoresis of complementary DNA of the proband, parents, and control (normal peer). P, proband; F, father; M, mother; C, control.

patients with MIA--CID, whereas non-truncating mutations tended to present as VEOIBD (Samuels et al., 2013; Avitzur et al., 2014). Nonsense mutations cause severe intestinal diseases (e.g., MIA) and CID; however, missense mutations mainly present as IBD and mild intestinal disease (Lawless et al., 2017; Neves et al., 2018). Our proband had a truncated mutation that affected the TPR domain, which manifested as neonatal-onset IBD and CID, but not as MIA. It is difficult to attribute complex phenotypes to physical alterations in *TTC7A*.

Fewer than 10% of patients with *TTC7A* mutations demonstrate VEOIBD with secretory diarrhea, chronic intestinal inflammation, lymphocytopenia, and/or hypoglobulinemia (Lien et al., 2017; Jardine et al., 2019a). Patients with VEOIBD are more likely to present with ileal involvement and isolated colonic involvement. Rectal bleeding and mucous stools with weight loss and underlying primary immunodeficiency appear to be more common in

VEOIBD cases with monogenic causes (Bequet et al., 2017; Kelsen et al., 2019; Shim, 2019).

Radiography and ultrasonography are the most commonly used methods of examination in pediatric patients, especially before the diagnosis of IBD. No specificity or significant differences between pediatric and adult IBD patients were identified (Horsthuis et al., 2008). Imaging studies of VEOIBD are relatively rare. Hepatosplenomegaly, significant intestinal wall thickening, and mildly dilated bowels are reported in neonatal IBD (Barber et al., 2018). In our proband, abdominal radiography revealed stiffness of the intestines and decreased intestinal gas volume. Gastrointestinal ultrasonography revealed thickening of the bowel wall, reduction in intestinal gas volume, and fluid accumulation in the colon. All these imaging findings were consistent with the pathologic changes of apoptosis, twisted crypts, and hypersecretion of mucus in the colon. It is very difficult to perform gastroenteroscopy (GE) in the early neonatal or infant stages because of the severe risk conditions, poor bowel preparation, and technical failure. The proband underwent GE at approximately 3 months of age, and chronic mild superficial inflammation in the esophagus, stomach, and duodenum, twisted crypts, and hypersecretion of mucus in the colon were observed. These features, unlike that in the atypical tissues observed in older children and adult ulcerative colitis or Crohn's disease, mainly involve the colon. Compared to that in adult IBD patients, extensive ileocolonic inflammation is more predominant in pediatric IBD patients (Peloquin et al., 2016). The most common endoscopic findings are mucosal bleeding among patients with VEOIBD and visual ileitis or ileocolonic bleeding in older patients with IBD (Conrad et al., 2019).

Severe chronic structural changes, increased frequency of apoptosis, blunt villi in the small intestine, and eosinophils in the surface epithelium, crypts, and lamina propria reported in VEOIBD are discovered in some primary immunodeficiencies (Conrad et al., 2019). T-cell maturation disruption and lymphocytopenia owing to a hypoplastic thymus and low blood immunoglobulin levels caused by increases in the relative levels of transitional B cells and B-cell receptor assembly and organelle

FIGURE 8 | mRNA relative expression of *TTC7A* vs. *ACTB* of the proband, parents, and control. ** $p < 0.01$. P, proband; F, father; M, mother; C, control.

synthesis in activated B cells are speculated (Avitzur et al., 2014; Woutsas et al., 2015). Therefore, immunodeficiency is closely related to VEOIBD; immune function should be tested as soon as possible during diagnosis. According to the data from our case, the phenotype involves extensive lesions in the stomach, duodenum, small intestine, and colon, leading to very early onset, severe symptoms, and immunodeficiency.

Most monogenic IBD patients are resistant to conventional medical treatment (Heyman et al., 2005; Kelsen et al., 2019; Shim, 2019), as are patients with neonatal-onset IBD with *TTC7A* deficiency. Currently, treatment options include early intestinal resection (in MIA), parenteral nutrition, and regular immunoglobulin infusion (Kammermeier et al., 2016). Total or partial parenteral nutrition has been reported in many patients with *TTC7A* mutations presenting with MIA, gastrointestinal defects, and IBD (Avitzur et al., 2014; Bigorgne et al., 2014; Lemoine et al., 2014); early application of parenteral nutrition is necessary because of intestinal malabsorption and excessive intestinal loss. In our study, parenteral nutritional support was initiated early.

VEOIBD shows poor response to immunosuppressives, steroids, and biologics (Jardine et al., 2019a). Hematopoietic stem cell transplantation treatment has been reported for monogenic IBD, which may restore immunity and increase survival in immunodeficient patients; however, it does not appear to improve the phenotypes associated with bowel epithelial defects (Jardine et al., 2019a). The survival rate of patients with *TTC7A* deficiency treated with HSCT did not improve (Kammermeier et al., 2016; Fayard et al., 2018). Intestinal and liver transplantation restores intestinal and immune functions in a child with MIA-CID (Gilroy et al., 2004). Unfortunately, intestinal transplantation is not feasible because of the limitations of donor factors. *In vitro* studies show that Rho A inhibitors (Y-27632) and leflunomide are effective treatments (Notarangelo, 2014; Jardine et al., 2019b); however, no *TTC7A*-deficient patients have received leflunomide. After we obtained consent from the parents, we started leflunomide treatment for 4 weeks but without any success. The efficacy of leflunomide *in vivo* is uncertain. Leflunomide is mainly used for treating rheumatoid arthritis. Leflunomide was effective in an *in vivo* zebrafish study on *TTC7A* deficiency; however, this drug was not effective in our proband. Further elucidation of the pathogenesis and therapeutic targets in *TTC7A*-deficiency through the accumulation of clinical experience is warranted. The infant died when treatment was stopped at the age of 5 months and 19 days.

The *TTC7A*-deficient genotype may be closely related to prognosis. The average survival of patients with *TTC7A* nonsense mutations is less than 12 months. Some patients with biallelic missense mutations that do not result in autoimmune disorders or involve TPR domains have a relatively better prognosis and can survive to adulthood (Lawless et al., 2017; Neves et al., 2018).

CONCLUSION

Two novel compound heterozygous mutations in *TTC7A* were identified for the first time in mainland China. These mutations manifested as neonatal-onset IBD-CID with a poor prognosis. No specific manifestations were found with imaging or endoscopy. Studying the genotype and clinical phenotype of *TTC7A* deficiency requires the accumulation of more clinical data and in-depth functional research.

DATA AVAILABILITY STATEMENT

The datasets for this article are not publicly available due to concerns regarding participant/patient anonymity. Requests to access the datasets should be directed to the corresponding authors.

ETHICS STATEMENT

The studies involving human participants were reviewed and approved by Women and Children's Hospital Ethics Committee, School of Medicine, Xiamen University. Written informed consent to participate in this study was provided by the participants' legal guardian/next of kin.

AUTHOR CONTRIBUTIONS

ML and YH conceived and planned this study and take full responsibility for this study; Y-eC, JC, and ML drafted this manuscript; Y-eC, JC, ML, JL, WG, HX, and TS contributed to clinical analysis; ML, YG, YH, and WZ contributed to the interpretation of results and genetic data; YZ reviewed the images; and JC contributed to the analysis of the endoscopic and histological data. All authors have contributed and approved the final manuscript.

FUNDING

This study was supported by the Xiamen Science and Technology Guiding Project (3502Z20199078 to ML) and the backbone talent cultivation project of the Xiamen Children's Hospital in 2019 (CHP-2019-BT-B001 to JC).

ACKNOWLEDGMENTS

We are very grateful to the infant and his family for their cooperation and contribution to this study. We would like to acknowledge Ying Huang (Children's Hospital of Fudan University, Shanghai, China) for her guidance regarding treatment.

Epigenetic regulation, particularly RNA m6 methyl adenosine (m6A) modification, plays an important role in the immune response. However, the regulatory role of m6A in the immune microenvironment in osteoarthritis (OA) remains unclear. Accordingly, we systematically studied RNA modification patterns mediated by 23 m6A regulators in 38 samples and discussed the characteristics of the immune microenvironment modified by m6A. Next, we constructed a novel OA m6A nomogram, an m6A-transcription factor-miRNA network, and a drug network. Healthy and OA samples showed distinct m6A regulatory factor expression patterns. *YTHDF3* expression was upregulated in OA samples and positively correlated with type II helper cells and *TGFb* family member receptors. Furthermore, three different RNA modification patterns were mediated by 23 m6A regulatory factors; in Mode 3, the expression levels of *YTHDF3*, type II T helper cells, and *TGFb* family member receptors were upregulated. Pathways related to endoplasmic reticulum oxidative stress and mitochondrial autophagy showed a strong correlation with the regulatory factors associated with Mode 3 and 23 m6A regulatory factors. Through RT-qPCR we validated that *SREBF2* and *EGR1* as transcription factors of *YTHDF3* and *IGF2BP3* are closely associated with the development of OA, hsa-miR-340 as a miRNA for *YTHDF3* and *IGF2BP3* was involved in the development of OA, we also detected the protein expression levels of *IGF2BP3*, *YTHDF3*, *EGR1* and *SREBF2* by western blotting, and the results were consistent with PCR. Overall, the constructed nomogram can facilitate the prediction of OA risk.

Keywords: epigenetics, immune microenvironment, RNA m6 methyl adenosine, osteoarthritis, RNA modification

INTRODUCTION

Osteoarthritis (OA) is a degenerative multifactorial disease that is characterized by progressive joint failure, which is often associated with joint pain, stiffness, and decreased range of motion (Lopes et al., 2017; Endisha et al., 2021). The pathological changes associated with OA include cartilage degeneration, synovitis, fibrosis, and subchondral bone sclerosis. The etiology of OA is complex and is currently thought to result from a combination of biomechanical processes, trauma, chronic inflammation, and immune response. Previous studies have shown that a variety of cells, cytokines,

chemokines, complements, and other immune system factors are involved in OA pathogenesis (Kandahari et al., 2015). However, studies on the role of m6A regulatory factors in the immune regulation of OA are scarce. Thus, further studies are needed in this regard.

N6 adenosine methylation (M6A), which is the most frequently observed RNA modification type, extensively occurs in mRNA, lncRNAs, and miRNAs. Specifically, M6A plays a crucial role in various physiological processes as well as in disease progression. Its modification is also a dynamic and reversible process controlled by different types of regulatory proteins, namely: methyltransferase (“writer”), demethylase (“erasers”), and the binding protein (“reader”). Furthermore, m6A modification is greatly affected by the expression and function of these regulatory proteins, and studying these regulatory proteins can enhance understanding of the role of m6A in gene regulation (Chong et al., 2021). It has also been observed that m6A modification under the influence of regulatory factors is associated with inflammation, the tumor microenvironment (TME), and immune response (Huang et al., 2021).

Previous studies have shown that m6A regulatory factors, especially *METTL3* and *FTO*, are involved in OA progression via the regulation of inflammatory response and extracellular matrix degradation. On the one hand, *FTO*-dependent m6A demethylation mediates the upregulation of *AC008*, which inhibits chondrocyte viability and promotes chondrocyte apoptosis and ECM degradation in OA (Yang et al., 2021). On the other hand, *METTL3* affects the stability of autophagy-related 7 (*ATG7*) mRNA, thereby influencing autophagic activity in an m6A- YTHDF2-dependent manner. This in turn promotes FLS fibroblast-like synovial cell senescence and OA progression (Chen et al., 2022). Further, *METTL3* regulates inflammatory responses in OA. It has also been observed that extracellular matrix degradation in OA is related to the balance between *TIMPs* and *MMPs*, which are regulated by *METTL3* (Sang et al., 2021). Furthermore, *METTL3* regulates cartilage tissue by regulating cartilage fine-cellular NF- κ B signal transduction, while ECM synthesis plays a mediator role in OA progression (Liu et al., 2019). Moreover, there is increasing evidence that m6A is involved in the regulation of immune responses (Zhang et al., 2021). Therefore, investigating the role of m6A regulatory factors in the immune response of OA and studying the differences in immune changes between healthy and OA tissues can improve our understanding of OA pathogenesis from a completely different perspective.

In this study, we systematically evaluated the modification patterns of m6A regulatory factors in OA. Thus, we found that m6A regulatory factors were distinguished between healthy and OA samples. The abundance of OA-infiltrating immune cells and the immune response genome were found to be significantly correlated with the m6A regulator, thus suggesting the existence of a strong correlation between m6A regulators and immune regulation. We also found different immune characteristics for different m6A molecular subtypes and analyzed their biological functions. These results indicated that the m6A modification pattern has a significant effect on the immune microenvironment in OA. We also constructed an m6A transcription factor-miRNA

network as well as a drug network. Simultaneously, a new m6A OA nomogram that can facilitate the prediction of OA risk was established.

MATERIALS AND METHODS

Data Acquisition and Difference Analysis

The relevant OA dataset, GSE114007 (Fisch et al., 2018), was downloaded from the GEO database. This dataset, with data platforms GPL11154 and GPL18573, consists of sequencing data corresponding to *Homo sapiens*. Further, this GSE114007 dataset includes 38 samples (including 18 control samples and 20 OA samples), all of which were included in this study. The R package DEseq2 (Love et al., 2014) was used to analyze differences in m6A gene expression values between the control and OA groups. The results of the different analyses were presented as heat maps and volcanic maps using R-package heat and ggplot2, respectively.

Analysis of m6A Regulatory Factors in OA

The expression relationships of 23 m6A regulatory factors in healthy and OA samples were evaluated using Spearman's correlation analysis. The random forest (Ishwaran and Lu, 2019) was first used to identify m6A regulators related to OA. Thereafter, the least absolute shrinkage and selection operator (LASSO) regression (Beinse et al., 2022) was used for feature selection, dimensionality reduction, and m6A regulator classifier developments. The distinguishing performances of the signature were then evaluated via receiver operating characteristic (ROC) curve analysis.

Analysis of the Correlation Between m6A Regulators and Immune Characteristics

Single-sample gene set enrichment analysis (ssGSEA) (Hanzelmann et al., 2013) was employed to estimate the number of specific infiltrating immune cells and the activity of specific immune responses. The absolute enrichment degree of a given gene set in each sample within a given dataset was expressed as an enrichment score. Further, gene listings for the gene set of infiltrating immune cells were obtained from previous studies (Shen et al., 2018; Zhang et al., 2020) and the immunoreaction gene set was obtained from the ImmPort database (<http://www.immport.org>) (Bhattacharya et al., 2014). The enrichment fraction represented the abundance of immune cells as well as the absolute enrichment of the immune response. The correlation of m6A regulators with immunocyte fractions and immune reaction activity was determined using Spearman's correlation analysis.

Identification of m6A Modification Pattern

Based on the expression of 23 m6A regulatory factors, different m6A modification patterns were identified via an unsupervised clustering analysis. Clustering was performed using R-package ConsensusClusterPlus (Wilkerson and Hayes, 2010). The number of clusters and robustness elation map of the patterns were also evaluated. Principal component analysis (PCA) further verified

the expression patterns of the 23 m6A regulators in the different modification modes. Kruskal–Wallis test was then performed to compare the expression of m6A regulatory factors, abundance scores of infiltrating immune cells, immune response scores, and HLA gene expression levels in the three different modification modes.

Biological Enrichment Analysis for Distinct m6A Modification Patterns

Biological signaling pathways may also reflect biological changes. Thus, we obtained the gene sets corresponding to “h.all.v7.0. symbols,” and “c5. go.v7.0. symbols” in the MSigDB database and converted the expression matrix into a pathway activation score matrix using the GSVA package. Thereafter, the activation scores of the two groups were compared using the R-package limma (Ritchie et al., 2015). Simultaneously, we also analyzed the correlation between the activation scores corresponding to the endoplasmic reticulum oxidative stress and mitochondrial autophagy pathways and the expression levels of m6A regulatory factors.

Transcription Factors: miRNA Networks and Drug-Compound Networks

We analyzed the targeted transcription factors, targeted miRNAs, and interacting drugs corresponding to high-expression genes in OA using the NetworkAnalyst database (Zhou et al., 2019), and thereafter constructed a network diagram.

Cartilage Donors

Normal human knee cartilage tissues were procured by tissue banks (approved by Scripps Institutional Review Board) from 5 females and 13 males (age 18–61, mean 38) without history of joint disease or trauma and processed within 24–48 h post mortem. Full thickness cartilage was harvested for RNA isolation from identical locations on the weightbearing regions on medial and lateral femoral condyles, and adjacent tissue sections were harvested for histology to verify the cartilage integrity. OA-affected cartilage was harvested from the tissue removed during knee replacement surgery from 12 female and 8 male donors (age 52–82, mean 66). Body mass indices between the normal ($BMI = 32.4 \pm 8.0$) and OA ($BMI = 30.7 \pm 8.1$) were not significantly ($p = 0.506$) different.

Tissue Processing, RNA and DNA Isolation

Cartilage was stored at -20°C in Allprotect Tissue Reagent (Qiagen, Valencia, CA) immediately after harvest until RNA extraction. For RNA isolation, a minimum of 150 mg of cartilage (dry weight) was pulverized using a 6770 Freezer/Mill Cryogenic Grinder (SPEX SamplePrep, Metuchen, NJ), and homogenized in Qiazol Lysis Reagent (Qiagen, Valencia, CA) at a concentration of 25 mg tissue sample per 700 μl Qiazol. To remove proteins and cellular debris, a initial phenol-chloroform extraction was performed. Briefly, samples were mixed with 0.2 volumes of chloroform, incubated for 5 min in ice, and

centrifuged at 14,000 rpm for 15 min at 4°C . The aqueous phase was collected, mixed with 1 volume of Qiazol and incubated for 30 min in ice. Then, samples were mixed with 1 volume of 100% ethanol, loaded into a mRNAeasy Mini kit column (Qiagen) and digested on-column with DNase following manufacturer instructions. RNA was eluted in 15 μl of RNase-free water. RNA purity was assessed using NanoDrop (ND-1000, Thermo Scientific, Wilmington, DE) and RNA integrity number (RIN) was calculated using a 2100 Bioanalyzer (Agilent, Santa Clara, CA). Average RIN numbers were 6.08 ± 0.95 .

Library Preparation and Sequencing

RNA samples from 18 normal and 20 OA cartilage donors were sequenced using 150 ng of total RNA as input. Sequencing mRNA libraries were prepared using the Encore Complete RNA-Seq DR Multiplex System 1–8 and 9–16 (NuGen, San Carlos, CA) with 16 unique indexed adapters (L2V6DR-BC2-L2V6DR-BC16). Two lanes of an Illumina HiSeq 2000 instrument were used to generate a total of 8–30 million 100 bp reads. The Illumina Genome Analyzer Pipeline Software (Casava v1.8.2) was used to convert the original image data generated by the sequencing machine into sequence data via base calling in order to generate fastq files and to demultiplex the samples. We performed a per base sequence quality check using the software FastQC (v0.10.1) (<http://www.bioinformatics.babraham.ac.uk/projects/fastqc/>) prior to read mapping. Raw RNAseq reads were aligned to the human genome (hg19) using the STAR aligner. The number of reads sequenced per sample ranged from 19 to 24 million reads, which should be sufficient for gene level quantification, but only 2–12 million reads per sample mapped to protein coding genes. To account for this issue, we applied high stringency the filtering of lowly expressed genes (log counts per million >3) so that only the differential expression analysis included only genes that were expressed in high enough abundances to be confident in their relative gene expression values.

Cell Culture

DMEM, 0.25% trypsin, and phosphate buffered saline (PBS) were equilibrated at room temperature and used for chondrocytes (Procell, Cat NO.: CP-H107, Wuhan, China) culture. Thereafter, the old medium was discarded and washed twice with PBS, which was followed by the addition of an appropriate amount of trypsin and digestion at 37°C for 1–2 min. The digestion was stopped by adding the culture medium, and the chondrocytes were then collected via blowing. The chondrocytes density was adjusted and the cells were inoculated into a 6-well plate, which was placed in an incubator at 37°C with 5% CO_2 ; the culture was incubated overnight. The next day, the cell culture plate was removed and washed with PBS three times; 1 ml of PBS was added in each wash cycle, and the resulting solution was shaken gently to avoid washing out the cells. Thereafter, the cells in the degeneration group were added to the medium containing IL-1 β (PEPROTECH) concentration of 40 ng/ml, while those in the control group were added to the normal medium. Culturing was then continued for 48 h.

Reverse Transcription-Quantitative Polymerase Chain Reaction (RT-qPCR)

Total RNA of 1*10⁶ cells was extracted using TRIzol reagent (15,596-026; Invitrogen, Carlsbad, CA, United States). A reverse transcription reaction system was constructed using the PrimeScript RT reagent kit with GDNase (# RR047A, Tokyo, Takara), and reverse transcription was performed onboard. The PCR system was constructed using the SYBR Green qPCR Mix (#D7260; Beyotime, Shanghai, China), and PCR detection was performed on a computer system. The 2- $\Delta\Delta C_t$ method was used to calculate the relative expression levels in the samples during RT-qPCR data processing. The primers used are listed in **Supplementary Table S1**.

Western Blotting

The total protein of 1*10⁶ cells was extracted using a whole cell lysis assay (KeyGEN Biotech, Nanjing, Jiangsu Province, China). Eighty micrograms of sample protein were subjected to SDS-PAGE (KeyGEN Biotech) and transferred to PVDF membranes (Millipore). The membranes were blocked and probed with the indicated primary antibodies at 4 °C for 12 h. The membranes were then incubated with the indicated HRP-conjugated secondary antibodies at room temperature for 2 h, and the expression of the target proteins was detected by ECL (KeyGEN Biotech). The following antibodies were used: IGF2BP3 (MA5-27484, 1:1000; Thermo Fisher), YTHDF3 (PA5-107309, 1:1000, Thermo Fisher), EGR1 (MA5-15008, 1:2000; Thermo Fisher), SREBF2 (1:2000; Thermo Fisher) and GAPDH (1:1000; Beyotime Biotechnology, Shanghai, China).

Statistical Analysis

All data calculations and statistical analyses were performed using R software (<https://www.r-project.org/>, version 4.0.2). Comparison between two groups of continuous normally distributed variables were realized by performing the independent Student's t-test, and the difference between non-normally distributed variables was analyzed using the Mann-Whitney U test (Wilcoxon rank-sum test). All statistical *p* values were bilateral, and statistical significance was set at *p* < 0.05.

RESULTS

Expression of the m6A-Related Genes in OA

Figure 1 shows the flowchart associated with the analysis of the expression of m6A-related genes in OA. To analyze the effect of m6A-related gene expression values on OA tissues relative to normal tissues, differentially expressed m6A-related genes in the dataset were obtained using the DESeq2 package and the results obtained were presented as a volcano plot (**Figure 2A**). From this figure, it is evident that OA showed high *IGF2BP3* and *YTHDF3* expression levels; significantly low *YTHDC1* expression levels; and low *WTAP*, *IGF2BP2*, *FMR1*, *RBM15*, *ALKBH5*, *LRPPRC*, *HNRNPC*, and *METTL14* expression levels. Meanwhile, a heat map (**Figure 2B**), chromosomal circos map (**Figure 2C**), and box map (**Figure 2D**) were generated based on the expression of m6A-related genes. As shown in the abovementioned figures, *YTHDC1*, *WTAP*, *IGF2BP2*, *FMR1*, *ALKBH5*, *LRPPRC*, *HNRNPC*, and *METTL14* showed low expression levels in OA.

Correlation Between the Expression Levels of the m6A-Related Genes in OA

To analyze the correlations between the expression levels of the m6A-related genes in OA, we performed correlation analysis on the expression levels of the m6A-related gene. In this regard, we used the corplot packet to plot the correlation results as a heat map (**Figure 3A**) and network map (**Figure 3B**). **Figures 3C–J** shows the scatter diagrams corresponding to the strongly correlated m6A-related genes in OA. Our results indicated that *METTL3* expression showed a strong correlation with *METTL14* expression, *KIAA1429* expression showed a strong correlation with *YTHDF3* expression, and *RBM15* expression showed a strong correlation with *WTAP* and *LRPPRC* expression. Additionally, *HNRNPA2B1* showed a strong correlation with *RBM15B* and *ALKBH5* expression, and *YTHDC2* showed a strong correlation with *RBM15* and *LRPPRC* expression.

Construction of an m6A Gene Prediction Model in OA

To analyze the resolution of OA by m6A regulatory factors, we first used the random forest method (**Figures 4A,B**). Samples were randomized into a training set (70%) and a verification set (30%), and the boxplots (**Figures 4C,D**) obtained thereafter showed significant differences in model scores between OA and healthy groups in the training and validation sets. Further,

the ROC curve (Figure 4E) showed that the model constructed using the random forest method exhibited a good diagnostic capability for OA; given that the results of the random forest analysis showed that all the m6A regulatory factors had good predictive power, we used Lasso regression analysis to characterize and reduce the m6A regulatory factors while excluding insignificant regulatory factors (Figures 5A,B). The obtained prediction model was: Risk Score = $CBL1 \times 2.731 + ZC3H13 \times 7.407 + YTHDF2 \times -0.732 + YTHDF3 \times 2.384 + YTHDC1 \times -12.361 + IGF2BP2 \times -5.030 + IGF2BP3 \times 2.051 + FMR1 \times -5.042$. Furthermore, the boxplot in Figure 5C showed a significant difference in risk scores between the OA and healthy groups. Subsequently, we constructed an OA risk-related nomogram (Figure 5D), which could distinguish between healthy and OA samples as a function of risk scores.

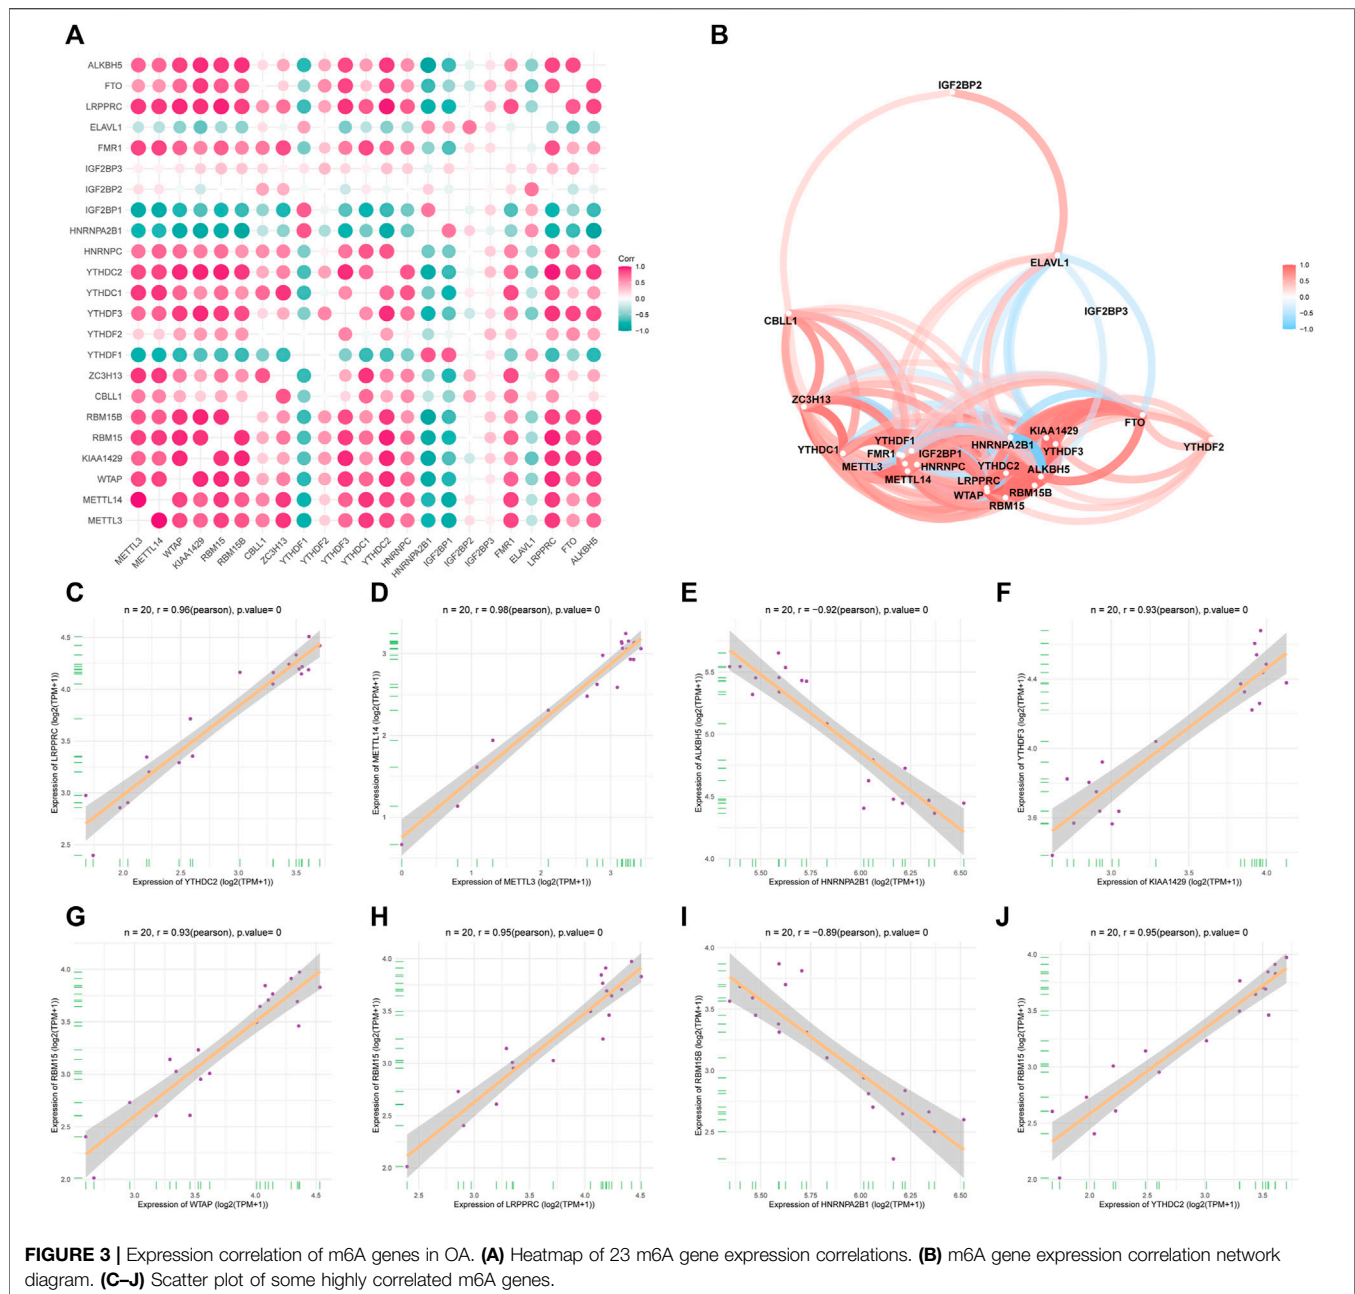

Correlation Between m6A Regulatory Factors in OA and Immune Cells and Immune Process

To investigate the correlation between m6A regulatory factors and the immune microenvironment, we performed a correlation analysis involving m6A regulators, infiltrating immunocytes, and immune

reaction gene sets (Figures 6A,B). The correlation analysis showed that m6A regulatory factors are strongly correlated with several immune cells. We also found that NK cells were positively correlated with most m6A regulatory factors, while NKT cells and CD8+T cells were negatively correlated with most m6A regulatory factors. Additionally, during the immune process, most of the m6A regulatory factors showed a negative correlation with cytokines and a positive correlation with receptors belonging to the TGFb family.

Modification Patterns of m6A RNA Methylation Mediated by 23 Regulatory Factors in OA

To investigate the m6A modification pattern of bones and joints, we performed unsupervised consensus clustering on OA samples based on the expression of 23 m6A regulatory factors (Figures 7A–E). The results thus obtained showed that clustering exhibited good stability at $K = 3$, and PCA revealed favorable differences among the three m6A molecular subtypes (Figure 7F). Further, the thermogram (Figure 7G) and boxplot (Figure 7H) show that the expression levels of the 23 m6A regulatory factors in the three m6A modification patterns were significantly different.

Immune Microenvironment Characteristics of Different m6A Modification Modes

To understand the differences in the immune microenvironment characteristics of different m6A modification modes, the infiltrating immune cells, immune response genome, and *HLA* gene expression were evaluated. Our results in this regard showed different immune cells for the three patterns (Supplementary Figure S1A). Compared to Modes 2 and 3, Mode 1 showed increased immunocytes infiltration; the number of CD4+T cells, immature dendritic cells, and natural killer cells corresponding to Mode 3 were higher than those corresponding to Mode 2. Additionally,

members of the TGF β receptor family showed high activity in Mode 3 (Supplementary Figure S1B), whereas the cytokine process in Mode 1 was relatively active. This was consistent with the previous analysis of the immune process. Similar trends were observed for *HLA* gene expression (Supplementary Figure S1C). In Mode 1, the overall expression of genes belonging to the *HLA* family was high. These results suggested that m6A modifications in Modes 1 and 3 mediated the master immune response, while the modification in Mode 2 mediated the mild immune response to OA. Further, the immune responses mediated by Modes 1 and 3 were different.

Biological Characteristics of Three m6A Modification Modes

To investigate the biological responses associated with the three m6A modification modes, we compared the HALLMARKS pathway and the GO pathway and evaluated the activation state of the biological pathway using GSVA enrichment analysis (**Supplementary Figures 2A–F**). Compared with Modes 1 and 3, relatively fewer pathways were enriched in Mode 2, thereby revealing the enrichment of pathways such as the ROS pathway. Meanwhile, Modes 1 and 3 were enriched in almost the same pathway. Specifically, Model 1 showed the enrichment of well-known pathways, such as the PI3K, AKT, and MTORC1 pathways, whereas Mode 3 showed the enrichment of pathways related to endoplasmic reticulum oxidative stress and mitochondrial autophagy. Previous studies have demonstrated that endoplasmic reticulum oxidative stress and mitochondrial autophagy play significant roles in OA; therefore, we investigated the correlation between m6A regulatory factors, endoplasmic reticulum oxidative stress, and mitochondrial autophagy pathway scores (**Figure 8A**). These results showed that the m6A regulatory factors were strongly correlated with endoplasmic reticulum oxidative stress and mitochondrial autophagy pathways (**Figures 8B–E**).

m6A-Related TF-MIRNA Network Construction and Drug Development for OA Treatment

In this study, we observed high *IGF2BP3* and *YTHDF3* expression levels in OA. Based on these two genes, we constructed a transcription factor-miRNA network and a drug-compound network diagram using the Network Analyst database. As shown in **Supplementary Figure S3A**, formaldehyde, C646, and other compounds can simultaneously act on these two regulatory factors. This observation suggests that formaldehyde and C646 compounds have the potential to be used as therapeutic drugs. As shown in **Supplementary Figure S3B**, *SREBF1*, *SREBF2*, and *EGR1* were identified as the common targeted transcription factors of the two genes, while hsa-miR-590-3p and hsa-miR-340 were identified as the commonly targeted miRNAs of the two genes.

RT-qPCR and Western Blotting

The expression levels of *IGF2BP3* and *YTHDF3* were upregulated in the IL-1 β -induced degeneration group (**Figures 9A,B**). This is consistent with the results of the

microarray analysis. Further, RT-qPCR results showed the expression of EGR1 and miR-340 of degeneration group was significantly decreased, while the expression of SREBF2 of degeneration group was upregulated (Figures 9C–E). These qPCR results for the two groups showed statistically significant differences. On the other hand, we also detected

the protein expression levels of IGF2BP3, YTHDF3, EGR1, and SREBF2 by western blotting, and the results were consistent with PCR, IGF2BP3, YTHDF3, and SREBF2 were upregulated in the IL-1 β -induced degeneration group, and the expression of EGR1 of degeneration group was significantly decreased. (Figure 9F).

FIGURE 9 | The mRNA or miRNA expression in the control and degeneration group. **(A,B)** Expression level of m6A genes in the control and degeneration group. **(C-E)** Expression level of m6A-related transcription factor and miRNA in the control and degeneration group. **(F)** Expression level of m6A protein and m6A-related transcription factor in the control and degeneration group. * $p < 0.05$ vs. Control.

DISCUSSION

OA is a disease that involves biomechanics, inflammation, and complex biological responses of the immune system (Woodell May and Sommerfeld, 2019). Presently, there are still many research gaps concerning the immune regulatory mechanism of OA, especially m6A regulatory factor-mediated immune regulation. In this study, we systematically investigated the modification pattern of m6A in the OA immune microenvironment; based on the results obtained, we arrived at the following conclusions:

First, we observed a difference in the expression of some m6A regulatory factors between healthy and OA samples, specifically the upregulation of *IGF2BP3* and *YTHDF3* in OA samples. Consistent results were obtained via RT-qPCR and WB, which validated our findings. These results indicated that m6A regulatory factors, especially *IGF2BP3* and *YTHDF3*, may be involved in OA development. Additionally, we observed the existence of correlations between the expression levels of m6A regulatory factors. Thus, we speculated that in OA, m6A regulatory factors jointly regulate OA progression through a regulatory network.

Next, we established an m6A classifier using m6A regulators that offer the possibility to distinguish between healthy and OA samples. This reaffirmed the important role of m6A regulatory factors in OA. Further, to improve and more conveniently predict OA, we established a new m6A nomogram. Based on the review

of relevant literature, we found that nomograms are rarely used to predict OA occurrence and progression. Daniel et al. developed a nomogram for diagnosing the rapid progression of knee osteoarthritis. Similarly, we established an m6A nomogram for predicting the risk of OA from the perspective of m6A modifications (Riddle et al., 2016). Different scores were assigned to factors such as age, sex, *CBL1*, *ZC3H13*, *YTHDF2*, *YTHDF3*, *YTHDC1*, *IGF1BP2*, *IGF2BP3*, and *FMRI*. The total score was obtained by adding the scores of each factor. The total score was less than 160, the probability of OA was less than 0.1, and probability of OA was greater than 0.9 if the total score was greater than 180.

Moreover, we investigated the association between m6A regulatory factors and the immune properties of OA, including the gene set for immune cell infiltration and immune response. We found that many m6A regulatory factors are closely related to these immune characteristics. Unsupervised clustering of periodontitis samples using m6A regulator expression profiles led to three subtypes with distinctive m6A modification patterns, and each subtype exhibited unique immune characteristics. Considering that each subtype has its immune characteristics, we believe that classification based on immunophenotypes of different m6A modulators is feasible. We believe that this classification strategy for immune subtypes will help in comprehensively understanding the mechanisms of immune regulation.

Notably, *YTHDF3* was upregulated in OA samples. In an immune correlation study, *YTHDF3* was positively correlated with type II T helper cells and TGF β family member receptors. In Mode 3, the expression of *YTHDF3*, type II T helper cells, and TGF β family member receptors were upregulated. Mode 3 could be enriched in pathways related to endoplasmic reticulum oxidative stress and mitochondrial autophagy. Meanwhile, we found that the m6A regulatory factor also had a strong correlation with endoplasmic reticulum oxidative stress and mitochondrial autophagy pathway, which is consistent with our previous study. Small extracellular vesicles-miR-151a-3p targeted *YTHDF3* to reduce the transcriptional inhibitory activity of SP3, promote the transactivation of TGF- β 1 in KCs, and then activate the SMAD2/3 pathway to enhance the stem cell-like characteristics of the incoming GC cells (Li et al., 2021). TGF- β 1 plays a vital role in maintaining the homeostasis of articular cartilage and subchondral bone (He et al., 2020). Apoptosis of articular chondrocytes is related to ROS-induced oxidative stress, which leads to mitochondrial damage and activates endoplasmic reticulum stress (Feng et al., 2019). Mitochondrial autophagy disorders in chondrocytes accelerate the development of OA (Wang et al., 2020). This suggests that *YTHDF3*, type II helper cells, TGF β family member receptors, endoplasmic reticulum oxidative stress, and mitochondrial autophagy pathways are closely related to OA.

Furthermore, we established a transcription factor-miRNA-m6A regulatory factor network and a drug-compound-m6A regulatory factor network. *SREBF1*, *SREBF2*, and *EGR1* are common transcription factors of *IGF2BP3* and *YTHDF3*, while hsa-miR-590-3p and hsa-miR-340 are two miRNAs that can be combined by both. Compounds such as formaldehyde and C646 can be combined with these two regulatory factors simultaneously.

SREBP-1 is a transcription factor responsible for the expression of enzymes involved in lipid and cholesterol homeostasis under sterol stimulation. The adsorption of glucose on chitosan membranes (CTS-Glc) stimulated the proliferation of human chondrocytes by providing energy through the regulation of lipogenesis via SREBP-1/Fans and promoting the cell cycle process through the expression of cell cycle regulators induced by *SREBP-1* (Chang et al., 2017).

The cholesterol regulatory element-binding factor-2 (*SREBF2*) gene is a well-known transcriptional regulator of the cholesterol biosynthesis genes. Stigmasterol (*STM*) reduces IL-1 β -induced *ATDC5* cell injury in mouse chondrocytes via *SREBF2*, and *STM* reduces il -1 β -induced *ATDC5* cell iron ptosis via *SREBF2* (Mo et al., 2021). *SIRT1* may aggravate osteoarthritis cartilage degeneration by activating the *SREBP2* protein-mediated PI3K/AKT signaling pathway (Yu et al., 2016).

EGR1 (early growth response 1) is a transcription factor of the c2h2 type zinc finger protein EGR family that regulates chondrocyte hypertrophy by activating the β -catenin signaling pathway (Sun et al., 2019). The *EGR1* gene has been identified as the central gene of OA development (Chen et al., 2021). *EGR1*, cartilage degeneration, and the expression of *EGR1* in the articular cartilage of OA patients increased (Huan et al., 2021). Mir-340-5p may inhibit the ERK signaling pathway through the *FMOD* gene, promote the proliferation of OA mouse chondrocytes, and inhibit apoptosis (Zhang et al., 2019).

To examine the expression of these genes in healthy and IL-1 β -induced osteoarthritis samples, we performed RT-qPCR and confirmed that *IGF2BP3* and *YTHDF3* were closely associated with the development of OA and *SREBF2*, *EGR1*, and miR-340 could be involved in OA progression by regulating the expression of *IGF2BP3* and *YTHDF3*. However, this study had some limitations. First, the data were downloaded from a public database and could not be evaluated for input errors. Second, based on bioinformatics analysis, RT-qPCR was used to detect the difference in molecular expression between OA and healthy samples; However, flow cytometry still need to be supplemented to verify the role of the molecules and the potential mechanism of OA. Single cells can also be sequenced to obtain the most accurate number of immune cells.

In conclusion, our study revealed a potential regulatory mechanism of m6A modification in the immune microenvironment of OA. Different modification modes of m6A cannot be ignored as they affect the immune microenvironment of OA, thus influencing the occurrence and development of OA. A comprehensive analysis of the modification mode of OA m6A in our study will help to understand the immune regulatory mechanism of OA, provide a reference for the treatment of OA, and supplement the research blank in this field. Meanwhile, the developed m6A OA nomogram can help assess the risk of OA, thus providing a reference for the clinical diagnosis of OA.

DATA AVAILABILITY STATEMENT

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found in the article/Supplementary Material.

AUTHOR CONTRIBUTIONS

YD and SN contributed to the study conception and design. Methodology and experiments were performed by YD and CY. Data collection and analysis were performed by MY and YO. The first draft of the manuscript was written by CY. YD and SN revised the manuscript. All authors read and approved the final manuscript.

ACKNOWLEDGMENTS

The authors acknowledge gratitude to all the staff who participated in the Study.

SUPPLEMENTARY MATERIAL

The Supplementary Material for this article can be found online at: <https://www.frontiersin.org/articles/10.3389/fgene.2022.921256/full#supplementary-material>

Background: The role of serum extracellular vesicles (EVs) is less known in
psoriasis.

Objectives: To explore the transcriptomic profile of serum EVs and the potential
biomarkers in psoriasis.

Methods: EVs were isolated by differential ultracentrifugation and identified by
transmission electron microscope. The diameters of EVs were detected using
nanoparticle tracking analysis. Serum EVs-keratinocyte interaction was
observed through confocal fluorescence microscopy. miRNA microarray and
mRNA microarray were performed in serum EVs ($n = 4$) and skin lesions ($n = 3$),
respectively. Quantitative reverse-transcriptase polymerase chain reaction
(qRT-PCR) and fluorescence *in situ* hybridization were used to detect the
expression of miRNAs in serum EVs and skin lesions ($n = 15$). Bioinformatics
analysis was performed to predict the potential target genes and functions of
miR-1305 and miR-6785-5p. Western blot, CCK-8 and enzyme-linked
immunosorbent assay (ELISA) were used to detect the EVs' biomarkers,
keratinocytes proliferation and cytokines secretion.

Results: A total of 16 miRNAs and 1,725 mRNAs were significantly dysregulated
in serum EVs and skin lesions, respectively. miR-1305 was down-regulated and
miR-6785-5p was upregulated in both serum EVs and skin lesions. Serum EVs
could be taken up by keratinocytes. miR-1305 was downregulated and miR-
6785-5p were upregulated in keratinocytes after co-cultured with psoriasis
serum EVs compared with controls. Psoriasis serum EVs promoted keratinocyte
proliferation and the secretion of CCL20 and IL-8. Serum EVs miR-1305 and
miR-6785-5p were associated with disease severity.

Conclusion: Serum EVs might be involved in the activation of keratinocytes
through loaded miRNAs in psoriasis. Serum EVs miR-1305 and miR-6785-5p
may be associated with psoriasis.

KEYWORDS

extracellular vesicles, miR-1305, MiR-6785-5p, psoriasis, inflammation

Introduction

Psoriasis is a chronic inflammatory skin disease (Srivastava et al., 2017; Nussbaum et al., 2021). The worldwide prevalence rate of this disease is about 2%–3% (Boehncke and Schon, 2015). Multiple factors contribute to the skin inflammation of psoriasis, including genetic, environmental, and immunologic triggers (Frischknecht et al., 2019; Griffiths et al., 2021). Psoriasis was proposed to result from a complex interplay among keratinocytes, immune cells and inflammatory mediators (Guinea-Viniegra et al., 2014). Keratinocytes are the main constituents of the epidermis and play an important role in the formation of psoriatic skin inflammation (Ni and Lai, 2020; Chen et al., 2021). Previous studies have suggested that the intercellular communication between keratinocytes and immune cells is mediated by proinflammatory cytokines (Than et al., 2019; Papayannakos et al., 2021). CCL20 and IL-8 secreted by keratinocytes play important roles in psoriasis, including the activation and chemotaxis of Th17 cells and neutrophils (Tsai and Tsai, 2017; Furue et al., 2020).

Recently, extracellular vesicles (EVs) are emerging mediators of intercellular communication between keratinocytes and immune cells, thought to participate in the pathogenesis of psoriasis (Shao et al., 2020). EVs are secreted from numerous cell types and have been isolated from a wide variety of human body fluids such as blood, urine, and saliva (Kim et al., 2017). EVs represent an important mode of intercellular communication by serving as vehicles for transfer between cells of membrane and cytosolic proteins, lipids, and RNA. Its functions depend on the ability of EVs to interact with recipient cells to deliver their contents (Raposo and Stoorvogel, 2013). A previous study has shown that keratinocyte-derived EVs promoted the Th1/Th17 polarization in psoriasis (Jiang et al., 2021). However, the characterization, transcriptomic profile and functional role of serum EVs in mediating keratinocyte activation and psoriatic skin inflammation are yet to be explored.

MicroRNAs (miRNAs) are 18–22-nucleotide, single-stranded, endogenous noncoding small RNA molecules. MiRNAs target mRNAs through complementary base pairing with 3'-UTRs of the target transcripts, in either a complete or incomplete fashion (Lu and Rothenberg, 2018). MiRNAs function by inhibiting mRNA translation and stability. Recently, miRNA dysregulation in the pathogenesis of psoriasis has attracted attention (Wu et al., 2018). However, little is known about the transcriptomic profile of miRNAs in serum EVs and the role of serum EVs miRNAs in the activation of keratinocytes in psoriasis.

Previous studies have confirmed the intrinsic cell targeting properties of EVs (Vader et al., 2016). However, recent studies mainly focused on the communication between EVs and neighbouring cells in psoriasis, such as T cells or neutrophils (Cheung et al., 2016; Shao et al., 2019). The communication between serum EVs and keratinocytes remains less known. As

the cell-targeting properties of EVs and the serum EVs-keratinocyte interaction were confirmed in this study, we assume that serum EVs might not only communicate with neighbouring cells but also communicate with keratinocytes in psoriasis.

In this study, we detected the characterization of serum EVs from psoriasis patients and healthy controls, and verified serum EVs could be taken up by keratinocytes through confocal fluorescence microscopy (CFM). To investigate the regulatory role of serum EVs in the activation of keratinocytes, we isolated serum EVs and performed a miRNA microarray. The mRNA microarray was also performed in skin lesions. In addition, we verified the role of serum EVs and the expression of serum EVs miR-1305 and miR-6785-5p. Previous studies suggest that miR-1305 and miR-6785-5p play important roles in diseases by regulating TGF- β 2/smad3 pathway, Wnt/beta-catenin pathway, Akt-signaling pathway and so on (Yu et al., 2019; Liu et al., 2020; Su et al., 2020; Kim et al., 2021). Furthermore, we found miR-1305 and miR-6785-5p might be involved in regulating inflammation response and correlated with the disease severity of psoriasis.

Our findings indicated a potential role of serum EVs in the epidermal hyperplasia and skin inflammation in psoriasis, opening the possibility that the serum EVs miRNAs might be as biomarkers and that serum EVs-keratinocytes interaction can be harnessed as a platform for innovative therapeutic strategies in psoriasis.

Materials and methods

Patients and tissue samples

Fifteen specimens were obtained from patients with psoriasis vulgaris (ten males and five females, aged 25–59 years). They had received no systemic treatments, phototherapy or externally used drugs for at least 1 month before skin biopsies and blood specimens collected. Ten control skin biopsies were obtained from healthy volunteers (five males and five females, aged 22–57 years). We obtained biopsies (1 × 0.5 cm) by surgical operations and whole blood (5–10 ml). Psoriasis Area Severity Index (PASI) was determined at the condition when samples were collected by at least two dermatologists. The study was approved by the ethics committee of Shandong University, China, and all patients provided written informed consent.

Serum extracellular vesicles extraction

Whole blood (5–10 ml) from patients and healthy controls were centrifuged at 3,000 rpm for 10 min to separate serum. The serum was collected, centrifuged at 300 g for 10 min, then at 16,500 g for 30 min, and later filtered through a 0.22 mm pore size filter to remove cell debris. The final supernatant was

ultracentrifuged at 100,000 g for 70 min and recentrifuged at the same speed. The purified EVs were resuspended in PBS.

Characterization of serum extracellular vesicles

Morphology of serum EVs was observed by transmission electron microscopy (TEM). The numbers and diameters were detected using nanoparticle tracking analysis (NTA, Zeta-View PMX 110; Particle Metrix, Meerbusch, Germany). Phenotypic was assessed by western blot using antibodies (Abcam) specific for CD9 (1:2,000, ab92726), CD63 (1:1,000, ab134045), and CD81 (1:1,000, ab109201).

miRNA and mRNA microarray analysis

Serum EVs miRNAs and mRNAs in skin lesions were detected using Agilent Human miRNA microarray V 21.0 (Sinotech Genomics, Shenzhen, China) and SBC Human (4 × 180K) competing endogenous (ce)RNA microarray (Shanghai Biotechnology Corporation, Shanghai, China), respectively. The fold change >2 in these analyses was an absolute value of fold change.

Fluorescence *in situ* hybridization analysis

A diluted double CY3-labelled miR-1305 probe (8 ng/μl, 5'-CY3-AAAAGTTGAGATTACCCTCTCT-CY3-3'; Servicebio, Wuhan, China) and miR-6785-5p probe (8 ng/μl, 5'-CY3-ACCCTCCCGCACCTACTACCAC-CY3-3'; Servicebio, Wuhan, China) were used for hybridization. 4',6-Diamidino-2-phenylindole (Servicebio, Wuhan, China) was used for nuclear staining.

Serum extracellular vesicles-keratinocytes interaction experiment

Serum EVs were labelled with PKH26 Red Fluorescent Cell Linker Mini kit (MINI26-1 KT; Sigma-Aldrich, St. Louis, MO) according to the instructions. Then, the suspension was centrifuged at 100,000 g for 70 min, and the supernatant was discarded. The labelled EVs were resuspended in PBS and centrifuged once again at the same speed. Next, the EVs were co-cultured with normal human epidermal keratinocytes (NHEKs) cells for 12 h. Then washed the cells 3 times with PBS and fixed with 4% formaldehyde. Subsequently, the cells were stained using phalloidin-iFluor 488 reagent, and DAPI was added to stain the nuclei. The cells were then observed under a confocal microscope (LSM800; Zeiss).

Quantitative reverse-transcriptase polymerase chain reaction

Serum EVs were digested with RNaseA (100 ng/ml, Qiagen, Australia). Then, total RNA from serum EVs was extracted using TRIzol reagent (Invitrogen). The expression levels of serum EVs miRNAs and miRNAs in skin lesions were detected according to the manual of the All-in-One miRNA qRT-PCR Detection System (GeneCopoeia, Guangzhou, China). U6 was used as the internal control for miRNA. Total RNAs from skin samples were extracted using an RNeasy mini kit (cat. no. 74106; Qiagen GmbH, Hilden, Germany) according to the manufacturer's protocols. Then the expression levels of mRNAs were detected using microarray analysis.

Western blot analysis

Western blot was performed as described in our previous experiments (Jiang et al., 2017; Zhao et al., 2017). The following primary antibodies were used in this study: rabbit monoclonal antibodies (procured from Abcam) specific for CD9 (1:2,000, ab92726), CD63 (1:1,000, ab134045) and CD81 (1:1,000, ab109201) and GAPDH (1:1,000, ab8245).

Bioinformatics analysis and miRNA-mRNA net-work analysis

Target genes of miRNAs were predicted using TargetScanHuman 7.1 and miRDB-MicroRNA Target Prediction Database. Then, the genes were intersected with mRNAs detected by mRNA microarray. Enrichment calculations were performed using Fisher's exact test. Further, we conducted GO and pathway enrichment analysis of the target genes. The specific principle was to carry out annotation mapping of differentially expressed genes in GO and KEGG database entries, calculate the number of the target genes in each GO and pathway entry, and then use hypergeometric test for statistics. Select the GO and KEGG entries that were significantly enriched in the differentially expressed genes. After the calculated *p*-value was corrected by multiple hypothesis tests, the *p*-value 0.05 was taken as the threshold, and the GO and KEGG term meeting this condition was defined as the GO and KEGG term significantly enriched in the target genes. MiRNA-mRNA network analysis was visualized using Cytoscape 3.9.0 software.

CCK-8 proliferation assay

The proliferation rates of NHEK Cells were measured at different time intervals using CCK-8 assays (Beyotime, Shanghai, China) after co-cultured with serum EVs obtained from psoriasis

FIGURE 1

Isolation and characterization of serum EVs. (A) Serum EVs were observed using transmission electron microscopy (scale bar, 200 nm). Serum EVs exhibited a typical artificial cup shape appearance; (B) the diameter of serum EVs was detected by nanoparticle tracking analysis ($n = 3$); (C) surface marker proteins of serum EVs were analyzed by western blot ($n = 3$), NHEKs and HaCat cells were used as positive controls. EVs: extracellular vesicles, scale bar = 200 nm.

patients ($n = 15$) and healthy controls ($n = 10$) for 12 h. Optical density (OD) values at 450 nm were measured using a Synergy H1 Microplate Reader (BioTek, United States).

Enzyme-linked immunosorbent assay

After 24 h co-cultured with serum EVs, the culture supernatants were collected. Then, the expression levels of CCL20 and IL-8 secreted from NHEK cells were measured using specific ELISA kits (Elabscience, China). Absorbance at 450 nm was measured using an ELISA plate reader (Bio-Rad).

Statistical analysis

All data are presented as mean \pm standard deviation. All experiments were performed at least 3 times. The differences between 2 groups were analyzed using Student's *t*-test with SPSS

17_0 analytical software (IBM, Armonk, NY, United States) and GraphPad Prism 7.00 (GraphPad Software, La Jolla, CA, United States). The target genes in GO and pathway were using hypergeometric test for statistics and *p*-value was corrected by multiple hypothesis tests. *p*-values < 0.05 were considered significant.

Results

Isolation and characterization of serum extracellular vesicles

To investigate the characterization of serum EVs in psoriasis, we isolated serum EVs from psoriasis patients and healthy controls using differential ultracentrifugation. Using the methods of transmission electron microscopy (TEM) and nanoparticle tracking analysis (NTA), we confirmed that purified serum EVs obtained from psoriasis patients and healthy controls both exhibited a typical cup-shaped structure

(Figure 1A), and their average diameters were around 100 nm (Figure 1B). In addition, as shown in Figure 1C, the expression of CD9, CD63, and CD81 was identified in serum EVs by western blot analysis.

Serum extracellular vesicles from psoriasis patients exhibit a specific miRNA profile

To determine miRNA profiling of serum EVs in psoriasis, the expression of EVs miRNAs was detected using miRNA microarray analysis ($n = 4$). The results showed remarkable differences in the serum EVs miRNA profiles, with

16 differentially expressed miRNAs in serum EVs from psoriasis compared with healthy controls (GSE200637). Among 16 differentially expressed miRNAs, 2 were upregulated and 14 were down-regulated (fold change > 2 , $p < 0.05$, Figures 2A,B), (Supplementary Table S1).

To further investigate the potential role of serum EVs miRNAs in the activation of keratinocytes, we performed mRNA microarray analysis in psoriatic skin lesions and healthy controls ($n = 3$). According to the mRNA microarray results, a total of 1,725 dysregulated mRNAs were identified. Among 1,725 dysregulated mRNAs, 1,157 mRNAs were upregulated and 568 mRNAs were downregulated (fold change > 2 , $p < 0.05$, Figures 2C,D), (Supplementary Table S2).

The mRNA microarray results suggested that there were a greater number of upregulated mRNAs in psoriatic skin lesions compared with healthy controls, which corresponded to the majority of miRNAs that were downregulated in serum EVs.

miRNA microarray validation

To validate the miRNA microarray results, we performed qRT-PCR ($n = 10$) and Fluorescence *in situ* hybridization ($n = 10$) to detect the expression of miR-1305 and miR-6785-5p which predicted closely related with inflammation responses. We digested EVs with RNaseA and reperformed qRT-PCR, the results indicated that miR-1305 and miR-6785-5p are present inside of EVs not on the surface of EVs (Figure 3A). The results of Figures 3B,C showed that the expression of miR-1305 was downregulated in both serum EVs and skin lesions (fold change = 0.2 in EVs, $p < 0.01$; fold change = 0.17 in skin lesions, $p < 0.001$) and miR-6785-5p was upregulated (fold change = 2.24 in EVs, $p < 0.001$; fold change = 2.76 in skin lesions, $p < 0.001$). As shown in Figures 3D,E, the results of fluorescence *in situ* hybridization (FISH) were consistent with qRT-PCR and showed that miR-1305 and miR-6785-5p were differentially expressed in the epidermis.

Potential functions of miR-1305 and miR-6785-5p

To explore the potential functions of differentially expressed miRNAs in serum EVs, we predicted the target genes of the validated miR-1305 and miR-6785-5p using bioinformatics analysis (TargetScanHuman 7.1 and miRDB-MicroRNA Target Prediction Database). As miR-1305 was downregulated and miR-6785-5p was upregulated in serum EVs and psoriatic skin lesions, the predicted target genes of miR-1305 and miR-6785-5p were intersected with upregulated and downregulated mRNAs which were detected by mRNA microarray (GSE181318), respectively. The results showed that 77 upregulated mRNAs might be regulated by miR-1305 and 83 downregulated mRNAs might be regulated by miR-6785-5p (Figures 4A,B); Supplementary Tables S3, S4). In addition, we mapped the miRNA-mRNA networks of miR-1305 and miR-6785-5p to study their regulatory mechanisms with the 77 upregulated mRNAs and 83 downregulated mRNAs, respectively (Figures 4C,D); Supplementary Tables S5,S6).

To clarify the potential biological functions of the 77 upregulated mRNAs and 83 downregulated mRNAs and the predicted involved signalling pathways, we annotated each gene of the intersection based on the Gene Ontology and KEGG

**FIGURE 4**

Predicted target genes of miR-1305 and miR-6785-5p, and miRNA-mRNA network analysis. (A,B) Target genes of miR-1305 and miR-6785-5p were predicted by TargetScan and miRDB, and then intersected with upregulated and downregulated mRNAs which detected by mRNA microarray respectively. (C,D) miRNA-mRNA network analysis of miR-1305 and miR-6785-5p. Red and green colours indicated high and low expression, respectively. miRNA: microRNA; EVs: extracellular vesicles. miRNA-mRNA net-work analysis was mapped using Zytoscape 3.9.0 software.

database. Then, GO analysis and KEGG pathway analysis were performed to predict the function of miR-1305 and miR-6785-5p, respectively. The results showed that both miR-1305 and miR-6785-5p were involved in regulating the inflammation response and the signalling pathway related to psoriasis, including positive regulating of type 1 interferon production,

autophagy, cytokine-cytokine receptor interaction, Th17 cell differentiation, IL-17 receptor activity, Wnt signalling pathway, MAPK signalling pathway and so on (Supplementary Figures S1A,D). These results indicated that miR-1305 and miR-6785-5p might be involved in the pathogenesis of psoriasis.

FIGURE 5

Serum EVs-keratinocytes interaction and serum EVs miR-1305 and miR-6785-5p might be biomarkers of psoriasis. (A) Uptake experiment of serum EVs; PKH26-labeled hucMSCs-Exo (red), cytoskeleton was labelled with phalloidin stain (green), and nuclei were stained with DAPI (blue). Scale bar = 50 μm; EVs: extracellular vesicles. (B,C) The expression of miR-1305 and miR6785-5p in NHEKs after co-cultured with serum EVs from psoriasis patients and controls. (D) The effects of serum EVs from psoriasis patients and controls on the proliferation of NHEKs. OD450: optical density measured at 450 nm. (E,F) The effects of serum EVs from psoriasis patients and controls on the secretion of CCL20 and IL-8 by NHEKs. (G,H) The expression of serum EVs miR-1305 and miR-6785-5p with PASI. miRNA: microRNA, PASI: plaques are graded based on three criteria: redness (R), thickness (T), and scaliness (S). Severity is rated for each index on a 0–4 scale (0 for no involvement; 4 for severe involvement). The body is divided into 4 regions: (h), upper extremities (u), trunk (t), and lower extremities (l). In each of these areas, the fraction of total surface area affected is graded on a 0–6 scale (0, no involvement; up to 6 for >90% involvement). The various body regions are weighted to reflect their respective proportion of body surface area. The composite PASI score can then be calculated: $PASI = 0.1(Rh + Th + Sh)Ah + 0.2(Ru + Tu + Su)Au + 0.3(Rt + Tt + St)At + 0.4(Rl + Tl + Sl)Al$.

Serum extracellular vesicles promote keratinocytes proliferation and inflammation response

To investigate whether serum EVs were involved in the activation of keratinocytes, we performed a serum EVs-keratinocytes interaction experiment. Purified serum EVs were isolated and

labelled with PKH26 Red Fluorescent. Next, the labelled EVs were co-cultured with NHEK cells for 12 h. Then, the cells were fixed with 4% formaldehyde and stained with phalloidin-iFluor 488 reagent and DAPI. Using a confocal microscope, we verified that serum EVs could be taken up by NHEK cells (Figure 5A).

Next, we detected the expression of miR-1305 and miR-6785-5p in NHEK cells after co-cultured with serum EVs obtained

from psoriasis patients and healthy controls. The results showed that miR-1305 was downregulated and miR-6785-5p was upregulated after co-cultured with serum EVs obtained from psoriasis compared with controls (Figures 5B,C). As the intrinsic cell targeting properties of EVs, our findings assumed that serum EVs might not only directly communicate with neighbouring cells, such as T cells or B cells, but also communicate with the activation of keratinocytes in psoriasis *via* the loaded miRNAs, including miR-1305 and miR-6785-5p.

Then, we explored the role of serum EVs in keratinocyte proliferation and inflammatory response. CCK-8 assay showed that serum EVs obtained from psoriasis significantly promoted the proliferation of keratinocytes compared with that of control groups (Figure 5D). Similarly, the results of ELISA analysis showed the secretion of CCL20 and IL-8 was significantly increased compared with that of control groups (Figures 5E,F). These findings suggested that serum EVs might be involved in the activation of keratinocytes in psoriasis.

Serum EVs miR-1305 and miR-6785-5p are related to the disease severity and might be biomarkers of psoriasis.

To further confirm the relationship of serum EVs miR-1305 and miR-6785-5p with the severity of psoriasis, we measured the correlation of miR-1305 and miR-6785-5p in serum EVs with PASI scores. As Figures 5G,H showed, the increase of miR-6785-5p was positively correlated with the PASI score. In contrast, the expression of miR-1305 in serum EVs was negatively correlated with disease severity. These results indicated that serum EVs miR-1305 and miR-6785-5p might serve as biomarkers of psoriasis.

Discussion

It is well known that a complex interplay among keratinocytes, immune cells and inflammatory mediators contributes to the pathogenesis of psoriasis (Raeber et al., 2018; Rendon and Schakel, 2019). In recent years, EVs have become a subject of intense study. EVs, such as microvesicles and exosomes, act as cell-to-cell communication vectors and potential biomarkers for diseases (Liu et al., 2019). The impacts of EVs transfer have been reported in many critical cellular processes including cell-to-cell communication and immune response regulation (Robbins et al., 2016). EVs are released by donor cells and can be taken up by recipient cells. EVs can carry RNAs and proteins which may affect the phenotype of the recipient cells (Mulcahy et al., 2014). Although the role of secreted cytokines and chemokines has been well documented in psoriasis, the potential role of EVs has not been sufficiently investigated in this disease (Deng et al., 2016; Yan et al., 2019). The communication between serum EVs and keratinocytes remains less known. Here, we found keratinocytes could take up serum EVs. In addition, considering the intrinsic cell targeting properties of EVs, we

assumed that serum EVs might be taken up by keratinocytes and serum EVs loaded miRNAs might be involved in regulating the mRNAs expression and activation of keratinocytes in psoriasis.

EVs are cell-secreted lipid bilayer membranous particles with heterogeneous size and composition (Li et al., 2020). They derive either from the endosomal compartment (exosomes) or as a result of shedding from the plasma membrane (microvesicles, endosomes and apoptotic bodies) (O'Brien et al., 2020). EVs may collapse during drying, resulting in a cup-shaped morphology (Raposo and Stoorvogel, 2013). The average diameter of EVs ranges from nanometres to a few micrometres, and the variety of their biological content includes lipids, proteins, and RNAs (Fabbiano et al., 2020). The major proteins involved with EVs biogenesis include CD63, CD81, CD9, etc (Veziroglu and Mias, 2020). Here in our study, using the methods of TEM and NTA, we verified that purified serum EVs exhibited a typical cup-shaped structure and the mean diameters were around 100 nm. In addition, the protein markers CD9, CD63, and CD81 were detected in serum EVs and the results were consistent with previous studies.

MiRNAs are important gene regulatory molecules and regulate vital cellular processes and inflammation regulation (Fabian et al., 2010). They modulate protein expression by inhibiting mRNA translation and stability. Our previous studies have verified that differentially expressed miRNAs in skin lesions were related to psoriasis, including miR-145-5p, miR-20a-3p, and miR-548a-3p (Li et al., 2018; Zhao et al., 2018; Yan et al., 2019). Recently, EVs miRNAs are considered to be involved in the pathogenesis of psoriasis. A previous study has identified that small EVs containing miR-381-3p from keratinocytes promotes Th1/Th17 polarization in psoriasis (Jiang et al., 2021). Another report identified circulating miRNAs in EVs as potential biomarkers for psoriatic arthritis in patients with psoriasis (Pasquali et al., 2020). However, the role of serum EVs in the pathogenesis of psoriasis remains less known.

Here, we found that miRNAs are indeed abnormally expressed in serum EVs in psoriasis. In addition, we confirmed that keratinocytes could take up the serum EVs. The result laid the foundation for studying the role of serum EVs in regulating the activation of keratinocytes and skin inflammation. As the intrinsic cell targeting properties of EVs, the results of miRNA microarray results and the EVs-keratinocytes interaction experiment indicated that there might be interactions between the dysregulated miRNAs derived from EVs and mRNAs in skin lesions. Furthermore, through the bioinformatics analysis, we found the dysregulated miRNAs derived from EVs might be involved in the activation of keratinocytes in psoriasis.

To further study the role of differential expression miRNAs derived from EVs in psoriasis, we found that miR-1305 and miR-6785-5p were closely related to inflammation response. Previous studies have reported that miR-1305 and miR-6785-5p play

important regulating roles in several diseases (Yu et al., 2019; Liu et al., 2020; Su et al., 2020). However, their functions in psoriasis have not been studied before. In this study, we found that miR-1305 and miR-6785-5p were participating in regulating inflammation response associated with psoriasis. Furthermore, the results of the bioinformatic analysis suggested that miR-1305 and miR-6785-5p might be involved in regulating the activation and differentiation of Th17 and Th1, which were not reported before. In addition, our findings indicated that miR-1305 and miR-6785-5p might play an important role in the pathogenesis of psoriasis (Chang et al., 2018; Roy et al., 2018; Wu et al., 2018).

It is generally accepted that EVs can be taken up and impact the functions of recipient cells. miRNAs in extracellular vesicles (EVs), may mediate paracrine and endocrine communication between different tissues and thus modulate gene expression and the function of distal cells (Mori et al., 2019). Here, we confirmed serum EVs regulated the expression of miR-1305 and miR-6785-5p in NHEKs and promoted NHEKs proliferation and proinflammatory cytokines secretion, including CCL20 and IL-8. CCL20 plays an important role in psoriasis by recruiting CCR6+Th17 cells into the lesional skin (Furue et al., 2020). IL-8 is also an important factor in psoriasis, which is characterized by proliferation of keratinocytes, neutrophil infiltration and angiogenesis (Wu et al., 2017). These results indicated that psoriasis serum EVs were involved in the activation of keratinocytes and skin inflammation in psoriasis. Furthermore, the functions of serum EVs may be through loading and transferring miR-1305 and miR-6785-5p.

Increasing studies have focused on extracellular miRNAs as potential biomarkers, since they are stable and can be detected in the blood, urine, or other body fluids (Grasedieck et al., 2012; Mori et al., 2019). In this study, by analyzing the correlation between the expression of serum EVs miR-1305 and miR-6785-5p with the Psoriasis Area and Severity Index (PASI) score, we found the expression of serum EVs miR-6785-5p was positively correlated with the PASI score. In contrast, the expression of serum EVs miR-1305 was negatively correlated with the PASI score. These results indicated that serum EVs miR-1305 and miR-6785-5p can be served as biomarkers in psoriasis. In addition, miR-1305 and miR-6785-5p may be potential candidates for therapy of psoriasis in the future.

However, this study also has some limitations. Firstly, the tissue sample sizes were relatively small, and larger samples are required in the future to verify our findings. Secondly, the biomarkers only focused on psoriasis. The specificity of the biomarkers miR-1305 and miR-6785-5p in other inflammatory diseases should be investigated. Thirdly, the molecular mechanism of miR-1305 and miR-6785-5p in psoriasis has not yet been fully revealed in this study, and the remaining 14 miRNAs were left out in this study, which limited the investigation of their functions in this study. Finally, due to

limitation of the sample size, we only showed the correlation of miR-1305 and miR-6785-5p in serum EVs with PASI scores.

Conclusion

In conclusion, the current study may suggest that serum EVs might be involved in the activation of keratinocytes through loaded miRNAs in psoriasis. Serum EVs miR-1305 and miR-6785-5p may be associated with psoriasis. This study may provide insight for further into the development and treatment of psoriasis.

Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by excessive activation of T and B lymphocytes and breakdown of immune tolerance to autoantigens. Despite several mechanisms including the genetic alterations and inflammatory responses have been reported, the overall signature genes in CD4⁺ T cells and how they affect the pathological process of SLE remain to be elucidated. This study aimed to identify the crucial genes, potential biological processes and pathways underlying SLE pathogenesis by integrated bioinformatics. The gene expression profiles of isolated peripheral CD4⁺ T cells from SLE patients with different disease activity and healthy controls (GSE97263) were analyzed, and 14 co-expression modules were identified using weighted gene co-expression network analysis (WGCNA). Some of these modules showed significantly positive or negative correlations with SLE disease activity, and primarily enriched in the regulation of type I interferon and immune responses. Next, combining time course sequencing (TCseq) with differentially expressed gene (DEG) analysis, crucial genes in lupus CD4⁺ T cells were revealed, including some interferon signature genes (ISGs). Among these genes, we identified 4 upregulated genes (*PLSCR1*, *IFI35*, *BATF2* and *CLDN5*) and 2 downregulated genes (*GDF7* and *DERL3*) as newfound key genes. The elevated genes showed close relationship with the SLE disease activity. In general, our study identified 6 novel biomarkers in CD4⁺ T cells that might contribute to the diagnosis and treatment of SLE.

KEYWORDS

systemic lupus erythematosus, CD4⁺ T cells, disease activity, weighted gene co-expression network analysis, biomarker, type I interferon, immune response

Abbreviations: BATF, basic leucine zipper transcription factor; BBB, brain-blood-barrier; DEG, differentially expressed gene; ER, endoplasmic reticulum; GO, Gene Ontology; HC, healthy controls; IFN, interferon; ISG, interferon signature gene; KEGG: Kyoto Encyclopedia of Genes and Genomes; LN: lupus nephritis; ME, module eigengene; NMI, N-myc-interactor; PBMC, peripheral blood mononuclear cell; PCA, principal component analysis; SLE, systemic lupus erythematosus; SLEDAI, systemic lupus erythematosus disease activity index; TCseq, time course sequencing analysis; TOM, topological overlap matrix; WGCNA, weighted gene co-expression network analysis.

Introduction

Systemic lupus erythematosus (SLE) is a chronic autoimmune disease which affects diffuse connective tissues and organs, including skin, joints and kidneys. SLE is characterized by excessive activation of T and B lymphocytes and breach of immune tolerance to autoantigens, which trigger the production of autoantibodies and lead to the immune-complex related inflammation in multiple organs and tissues (Tsokos, 2011). Genetic factors and environmental triggers are believed to play important roles in the pathogenesis and progression of SLE (Goulielmos et al., 2018; Dorner and Furie, 2019). Nevertheless, the pathogenic mechanisms of SLE have not been fully understood yet. Thus, the time-course of disease flares, remission and progression is unpredictable (Obermoser and Pascual, 2010). Besides, SLE is also a highly heterogeneous disease in terms of diverse clinical manifestations and severity, which presents a challenge to the clinicians and researchers. It would therefore be of great value to explore the molecular signatures underlying different clinical phenotypes, as it could aid in accurate diagnosis, disease activity assessment and clinical management of SLE.

The mutation and abnormal expression of many vital genes also confer a predisposition to SLE, indicating the value of diagnosis or prognosis (Teruel and Alarcon-Riquelme, 2016; Luo et al., 2020). However, peripheral blood mononuclear cells (PBMCs) consist of a mixture of lymphocytes and monocytes, and rarely show a good enough discrepancy on transcriptomic profiles. Among the major peripheral immune cells in lupus, the autoreactive and pro-inflammatory CD4⁺ T cells stimulate the differentiation, proliferation and maturation of B cells to enhance the production of autoantibodies, playing a key role in the pathogenesis and progression of SLE (Moulton and Tsokos, 2011; Zhao et al., 2018; Jang et al., 2021). The alterations in the signaling physiology and gene transcription lead to abnormalities in the phenotype of these cells (Mak and Kow, 2014; Yuan et al., 2022). Most of all, the peripheral blood cells of lupus patients demonstrated overexpression of the gene profiles induced by type I interferon (IFN), also known as interferon signature genes (ISGs) (Feng et al., 2015; Ronnblom, 2016; Postal et al., 2020). However, how these molecular signatures correlate with SLE activity awaits further characterization. The transcriptomic or translational profiles of lupus CD4⁺ T cells can lead to a better understanding of pathogenic mechanisms of SLE, and aid in potential therapeutic targets identification in an unbiased manner.

Weighted gene co-expression network analysis (WGCNA) is a well-known method of systems biology for exploring and identifying the potential functional pathways and biomarkers for diagnosis and prognosis of complex diseases at the level of the genome (Langfelder and Horvath, 2008). This powerful bioinformatic tool has been widely used in various diseases,

including SLE and other autoimmune diseases (Yan et al., 2018; Sun et al., 2019). Using WGCNA, Liu et al. found overexpressed small RNAs encoded by human endogenous retrovirus K in PBMCs that might be involved in the immune regulation and progression of SLE (Liu et al., 2021). Similarly, *IFI27* may be closely related to pathogenesis of SLE (Zhao et al., 2021). In lupus nephritis (LN), the potential gene expression biomarkers for diagnosis and prognosis were developed by integrating multiple differentially expressed gene (DEG) identification methods (Yao et al., 2020; Chen et al., 2021; Shen et al., 2021). In this study, through integrated bioinformatics analysis of high-throughput sequencing data, we well-characterized the gene expression profiles in CD4⁺ T cells obtained from healthy controls (HC) and lupus patients, and identified crucial genes correlated with the severity of SLE. These findings could improve our understanding of the disease pathogenesis and provide new insights in identification of potential diagnostic and therapeutic molecular targets of SLE.

Materials and methods

Data acquisition and processing

We obtained the gene expression dataset GSE97263 with corresponding clinical information from the GEO database (<https://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE97263>), which was performed with the platform of Illumina HiSeq 2500. This dataset contained isolated blood CD4⁺ T cells from 14 HC, 14 active and 16 inactive SLE patients (Buang et al., 2021). The Systemic Lupus Erythematosus Disease Activity Index (SLEDAI score) was used for clinical classification. Inactive SLE was defined as a SLEDAI <4 and active SLEDAI >6. Processing and analysis of these collected data were conducted with the R software. The Ensemble IDs were converted into gene symbols with the *bitr* function in *clusterProfiler* (Wu et al., 2021), and the genes with average raw reads value less than 1 were removed. After data processing, 16,623 genes were matched, and all these genes were used for the following WGCNA after normalized with log transformed (in detail, $\log(\text{edgeR:cpm}(\text{counts}+1))$).

WGCNA

A sample clustering tree map was first constructed to detect and eliminate outliers. Then, the “WGCNA” R package (Langfelder and Horvath, 2008) was used to construct the gene network with the dataset GSE97263. In detail, scale independence and mean connectivity were identified *via* the soft threshold power (β value) setting of 1–20. Meanwhile, soft threshold power was selected as the degree of scale

independence reached 0.85. Based on the selected soft threshold, the adjacency matrix was converted to topological overlap matrix (TOM) to construct the network. Then, we performed module identification using `cutreeDynamic` function with `minClusterSize = 100`, and the gene dendrogram and module color were established using the degree of TOM-based dissimilarity(1-TOM). Next, `MergeCutHeight` function was used for cutting the dendrogram in the process of module merging with the a 0.25 `MEDissThres` value, and 14 modules were finally harvested.

Identification of clinically significant modules

The Pearson correlation coefficient between the module eigengene (ME) and sample traits was calculated to find out the highly relevant module (hub module) associated with the development of SLE. Modules with top 2 corresponding correlation with $p < 0.05$ were identified. Then the relationship between Module Membership (MM, the correlation of the module eigengene and the gene expression profile) and Gene Significance (GS, the correlation between the gene and the clinical phenotypes) in these modules was calculated and visualized with the “WGCNA” R package (Langfelder and Horvath, 2008). The significantly correlation GS and MM implied that hub genes of the modules tend to be highly correlated with clinical phenotypes.

Functional enrichment analysis

In order to identify the function of the selected genes in the pathogenesis and development of SLE, Kyoto Encyclopedia of Genes and Genomes (KEGG) and Gene Ontology (GO) enrichment analysis of gene functions in hub modules were performed using the “clusterProfiler” R package (Wu et al., 2021) with the default parameters.

Identification of DEGs in HC, inactive and active SLE

The “DESeq2” R package was used to identify DEGs among the three groups with the threshold of $|\log_2FC| > 1$ and $p < 0.05$. Besides, the “TCseq” R package “timeclust” function was used to characterize the gene expression patterns in three groups following the manuscript (DOI: 10.18129/B9.bioc.TCseq). The clusters that showed positive or negative relations with SLE activity were selected.

Identification of key genes

The Jvenn web tool was used to identify the overlapped intersection of the genes identified by WGCNA, time course sequencing (TCseq) and DEG analysis. These key genes were selected to perform principal component analysis (PCA) and heatmap analysis for validation.

Identification of potential biomarkers of SLE

First, we analyzed the key genes identified above with the “clusterProfiler” R package (Wu et al., 2021), and identified the genes that participated in regulation of top GO terms related to the development of SLE. Then, we compared the gene expression between HC and SLE patients with different disease activity and identified the potential biomarkers of diagnostic and therapeutic value for SLE.

Statistical analysis

All the statistical process and analysis in this manuscript were performed with R software, and $p < 0.05$ was considered as statistically significant.

Results

Gene expression profiles in HC, inactive and active SLE

Herein, 44 isolated CD4⁺ T cells samples obtained from the dataset GSE97263 were processed. A total of 41,092 Ensemble IDs were converted into gene symbols. As the genes with average raw reads less than 1 were removed, 16,623 genes were selected for the following analysis. After data processing, we examined the gene expression differences in CD4⁺ T cell isolated from HC and SLE patients with different disease activity (Figure 1). According to the PCA results, the gene signatures of these three groups could not be clearly separated (Figure 2A). Next, we analyzed the differences between HC and active SLE group, and found 834 upregulated genes and 252 downregulated genes, with the cut-off criteria of $p < 0.05$ and $|\log_2FC| > 1$ (Figure 2B). Similarly, the volcano plots showed the difference of DEGs between HC and inactive SLE (Figure 2C), and inactive and active SLE group (Figure 2D). Next, the genes with the largest variance of gene expression were selected for heatmapping, as shown in the Supplementary Figure S1, indicating dynamic changes in gene expression during the development of SLE.

Identification of hub modules through WGCNA

With no outlier samples, we calculated the optimal soft threshold power (β value) was 8, which was verified by scale-free topology analysis with $R^2 = 0.85$ (Supplementary Figures S2A,B). After merging similar modules with the cut-off value = 0.25, 14 modules from the weighted co-expression network were identified based on all the 16,623 genes (Supplementary Figures S2C,D). The gene numbers and detailed symbols in each module were shown in Supplementary Figure S2E and Supplementary Table S1, respectively. In order to explore the relationships among the above-mentioned modules, we quantified the module similarity by eigengene correlation, and the TOM heatmap showed strong correlation within the module groups (Supplementary Figures S2F).

Correlation between modules of interest and clinical traits

Next, identifying modules most associated with the disease activity is of great biological significance for biomarker development. According to the module-trait relationships in Figure 3A, the MELightcyan and

MEsalmon modules were negatively related to disease activity ($\text{Cor} = -0.45$, $p = 0.002$ for MELightcyan, and $\text{Cor} = -0.43$, $p = 0.004$ for MEsalmon), while the MEcyan and MEbrown modules displayed positive relationship with disease activity ($\text{Cor} = 0.7$, $p = 1 \times 10^{-7}$ for MEcyan, and $\text{Cor} = 0.69$, $p = 3 \times 10^{-4}$ for MEbrown). Thus, these modules were selected for downstream analysis. As shown in Figures 3B–E, GS and MM were highly correlated, illustrating that genes significantly associated with disease activity were also the central elements of modules highly associated with this trait.

Functional analysis of hub modules

To investigate the correlated biological processes, GO enrichment analysis was carried out on all matched genes in these modules (Supplementary Table S2). In the salmon module, the enriched biological processes were mainly associated with nuclear-transcribed mRNA catabolic process (nonsense mediated decay), cotranslational protein targeting to membrane, SRP-dependent cotranslational protein targeting to membrane and translational initiation. In the cyan module, the biological processes were mainly enriched in the regulation of type I IFN production and response to IFN- α (Figure 3F).

FIGURE 2

The DEG analysis showed the differences of gene expression profiles in HC, inactive and active SLE patients. **(A)** The PCA result of the gene expression of CD4⁺ T cells in HC, inactive and active SLE patients. **(B–D)** The volcano plot of DEGs between HC and active SLE **(B)**, HC and inactive SLE **(C)**, and inactive SLE and active SLE **(D)**.

Identification of gene sets related to SLE disease activity

The above WGCNA results showed that the gene expression patterns of hub modules were significantly correlated with disease activity. To further clarify the gene sets closely related to SLE, TCseq analysis was used to analyze CD4⁺ T cells from SLE patients with different disease activity. The detailed gene symbols in different clusters were listed in [Supplementary Table S3](#). The results showed that the Cluster2 was positively correlated with SLE disease activity, while the Cluster3 was negatively related to the disease activity ([Figure 4A](#)). In KEGG enrichment analysis, we found that genes in the Cluster2, which were upregulated in SLE patients, were enriched in the pathways of cell cycle, necroptosis and p53 signaling. The GO analysis showed that

these genes were enriched in T cell activation, DNA replication, regulation of innate immune response, type I IFN production, response to type I IFN and T cell migration ([Figure 4B](#)). In the Cluster3, the KEGG analysis showed that the downregulated genes were enriched in multiple signaling pathways, including Wnt and transforming growth factor-beta (TGF- β) signaling pathways. The GO analysis also revealed that these genes were related to positive regulation of cell projection organization, canonical Wnt signaling pathway, positive regulation of growth and positive regulation of protein binding ([Figure 4C](#)).

Based on combined analysis of WGCNA, TCseq and DEG, 146 genes showed positive correlation with disease activity and 51 genes showed negative correlation with disease activity in patients ([Figures 5A,B](#)). Therefore, these 197 genes could be used to distinguish active and inactive SLE patients ([Figures](#)

FIGURE 3

Main findings in the module-trait correlations through WGCNA. (A) Module-trait associations. Each row corresponded to a module eigengene (ME), while each column corresponded to a trait. Each cell contained the corresponding correlation and p value. The cells were color-coded by correlation according to the color legend. (B–E) The scatterplots of Gene Significance (GS) for disease activity vs. Module Membership (MM) in the lightcyan (B), salmon (C), cyan (D) and brown module (E), which represented significant correlations between GS and MM in these modules. (F) The dot plot of GO enrichment analysis of the genes in different modules.

FIGURE 4 Identification of gene sets related to SLE disease activity. **(A)** Clustering of the gene expression patterns in CD4⁺ T cells from HC, inactive and active SLE patients by TCseq analysis. A total of 9 clusters were obtained and the Cluster 2 and 3 were found significantly correlated with SLE disease activity. **(B)** KEGG (left) and GO (right) analysis of genes in the Cluster 2. **(C)** KEGG (left) and GO (right) analysis of genes in the Cluster 3.

5C,D). We further analyzed the biological functions of these identified genes and found that they were enriched in the response to type I IFN, IFN- β production, negative regulation of T cell proliferation and immune system process (Figures 5E,F).

Identification of the potential biomarkers for SLE

The genes upregulated in SLE patients mainly focused on type I IFN response. We found 24 ISGs (*RSAD2*, *IFIT3*, *APOBEC3A*, *IFIT2*,

PARP9, *DTX3L*, *PLSCR1*, *IFI35*, *ISG15*, *CMPK2*, *HERC5*, *GBP1*, *IFI27*, *STAT1*, *MX1*, *IRF7*, *OAS1*, *OAS2*, *OAS3*, *OASL*, *IFIH1*, *SIGLEC1*, *LGALS9* and *BST2*) which were significantly associated with SLE disease activity (Figures 6A,B, Supplementary Figure S3). Among them, *PLSCR1* and *IFI35* were identified as the newfound crucial ISGs. Besides, *BATF2* and *CLDN5* were also identified as key genes (Figure 6C). The expression levels of the above genes were significantly upregulated, especially in those active SLE patients. On the other hand, the expression of *GDF7* and *DERL3* showed significant decrease in active or inactive SLE, compared with that in HC group (Figure 6D). The

relevant research in other diseases also pointed that the 4 upregulated genes (*PLSCR1*, *IFI35*, *BATF2* and *CLDN5*) and 2 downregulated genes (*GDF7* and *DERL3*) exhibited immunoregulatory functions. Therefore, these 6 newfound genes may serve as potential biomarkers of SLE.

Discussion

It has been reported that lupus CD4⁺ T cells had altered signaling and function, and the hyperactivation of these cells was

an important molecular feature of SLE patients. In this study, we analyzed the expression patterns of CD4⁺ T cell in HC, inactive and active SLE through multiple analysis methods, and explored the molecular indicators for potential diagnostic biomarkers and therapeutic targets of SLE.

From methodology aspect, DEG analysis focuses on the differentially expressed genes among different groups, while WGCNA focuses on the correlations between the co-expression modules and the phenotypic and clinical traits, not merely the differences in gene expression profiles. TCseq can be applied for differential analysis between different time points and temporal pattern analysis and visualization of sequencing data. These three bioinformatical tools are complementary to one another to describe key relevant patterns to expanding our capacity for identifying novel biomarkers. In this study, through WGCNA analysis, we established gene expression module-disease activity relationship and found the main functional enrichment in the cyan module included regulation of type I IFN production and the IFN response. This observation is consistent with the current knowledge that ISGs are highly related with SLE disease activity (Crow, 2014; Gkirtzimanaki et al., 2018; Buang et al., 2021). From the perspective of treatment, monoclonal antibodies such as Anifrolumab (Anderson and Furie, 2020; Tanaka and Tummala, 2021) and Sifalimumab (Greth et al., 2017), which block the activation of type I IFNs, have demonstrated significant effectiveness in achieving the composite endpoints in active SLE patients. The medical researchers have also tried to treat lupus by inhibiting type I IFNs in a variety of ways, such as glucocorticoids (Kirou and Gkrouzman, 2013), nicotinamide riboside (Wu et al., 2022) and mTOR inhibitor (Murayama et al., 2020). On the other hand, the salmon module was enriched in biological processes of translational initiation and cotranslational protein targeting to membrane, showing that the expression level negatively correlated with disease activity. The major consequence of perturbing cotranslational targeting for disease progression is so far largely unexploited. We speculate that it may be involved in T cell differentiation, which accompanied by the expression and secretion of a large number of cytokines, as well as communication between cells.

Furtherly, by combining the TCseq with DEG analysis, we identified the presence of 197 genes as closely correlated with disease activity in patients, that may play an integral role in the development of SLE. GO analysis showed that DEGs were mainly involved in negative regulation of immune system process, the response to type I IFN, IFN- β production and negative regulation of T cell proliferation. A total of 24 ISGs showed significant upregulation in SLE patients, especially in those who presented with higher disease activity. The results are consistent with the phenomenon of over-activated IFN response in lupus patients, and further confirm that ISGs play a vital role in the pathogenesis of SLE. Among these ISGs, we identified *PLSCR1* and *IFI35* as the

newfound crucial genes. *PLSCR1* is a member of the phospholipid scramblases protein family and involved in regulating phospholipid movements within the plasma membrane. Several reports found that significant hypomethylation of differentially methylated sites in SLE was associated with *PLSCR1* (Yeung et al., 2017; Joseph et al., 2019; He et al., 2022). Besides, elevated expression of *PLSCR1* was found in monocytes from SLE patients (Suzuki et al., 2010), and it was also involved in the modulation of the phagocytic process in differentiated macrophages (Herate et al., 2016). *IFI35* reflects the type I IFN activity induced through the JAK-STAT phosphorylation (De Masi et al., 2021). Elevated expression levels of *IFI35* were found in serum of LN patients, which promoted LPS-caused inflammatory response and cell apoptosis (Zhang et al., 2021). *IFI35* also showed regulatory effects on multiple immune cells by activating macrophages and dendritic cells and promoting naïve T cell differentiation into Th1 and Th17 cells (Xiahou et al., 2017; Jing et al., 2021). A significant elevation in *IFI35* expression in active SLE was also found in our study, indicating that *IFI35* may be associated with the dysregulation of host IFN production and immune cell function in SLE.

Besides, we also explored upregulated *BATF2* and *CLDN5* as critical genes in SLE. *BATF2* was significantly induced and involved in gene regulation of IFN- γ -activated classical macrophages (Roy et al., 2015), and inhibited Th17 responses by suppressing IL-23a expression (Kitada et al., 2017; Kayama et al., 2019). In SLE, *in vitro* experiments indicated *BATF2* may be involved in the impairment of translational and proliferative responses to mitogens in T cells (Ge et al., 2021). *CLDN5* encodes tight junction protein and plays a role in C5a/C5aR1 signaling, which was reported to be related to the impaired brain-blood-barrier (BBB) in SLE with neurological complications (Mahajan et al., 2015). These abnormal expression patterns may eventually disturb immune function with CD4⁺ T cells activation and proliferation. Among these downregulated genes, we identified *GDF7* and *DERL3* as key genes. *GDF7* encodes a secreted ligand of the TGF- β superfamily of proteins. Recent research showed that *GDF7* can exhibit positive regulatory effects on Tregs via increasing the expression of *FOXP3* and *CTLA4* (Ding et al., 2021). Thus, the downregulation of *GDF7* in CD4⁺ T cells may lead to impaired suppressive functions of lupus Tregs. *DERL3* encodes proteins belong to the derlin family, which resides in the endoplasmic reticulum (ER). Recent reports using WGCNA or RNA-seq suggested that the function of *DERL3* may correlate with plasma cells (Gao et al., 2022; da Silva et al., 2020). Since CD4⁺ T cells act as main helper cells for plasma cell production and cytokines secretion, we suggest that the decreased expression of *DERL3* in lupus CD4⁺ T cells may contribute to the pathogenesis of SLE. Taken together, our data indicated the potential diagnostic and therapeutic value of *GDF7* and *DERL3* in SLE.

There are still several limitations in this study. First of all, the diagnostic or prognostic value of these key genes require a large number of blood samples for validation. Secondly, we did not further clarify the molecular mechanisms of the identified genes. Finally, although we have performed a detailed bioinformatics analysis, some vital genes in the pathogenesis and progression of SLE may still be missed. Thus, further analysis and detailed experiments are needed to definitely establish the predictive biomarkers and explicitly evaluate the performance.

In summary, based on integrated bioinformatical analysis, we found gene sets highly related to SLE disease activity. Besides, some crucial genes mediating the development of SLE were identified, including some previously reported ISGs. In particular, we found 4 upregulated genes (*PLSCR1*, *IFI35*, *BATF2* and *CLDN5*) and downregulated expression of *GDF7* and *DERL3* in SLE patients. Therefore, our findings identified 6 novel potential biomarkers in lupus CD4⁺ T cells, which provided new insights into the development and treatment of SLE. The underlying mechanisms of these genes are still need to be further explored.

Data availability statement

Publicly available datasets were analyzed in this study. This data can be found here: <https://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE97263>.

Author contributions

ZL, ZW and LS contributed to conception and design of the study. ZL and ZW organized the database, performed the statistical analysis and wrote the first draft of the manuscript. All authors contributed to manuscript revision, read, and approved the submitted version.

Psoriasis is an immune-mediated chronic inflammatory skin disease caused by a combination of environmental incentives, polygenic genetic control, and immune regulation. The inflammation-related gene absent in melanoma 2 (*AIM2*) was identified as a susceptibility gene for psoriasis. *AIM2* inflammasome formed from the combination of *AIM2*, PYD-linked apoptosis-associated speck-like protein (ASC) and Caspase-1 promotes the maturation and release of inflammatory cytokines such as IL-1 β and IL-18, and triggers an inflammatory response. Studies showed the genetic and epigenetic associations between *AIM2* gene and psoriasis. *AIM2* gene has an essential role in the occurrence and development of psoriasis, and the inhibitors of *AIM2* inflammasome will be new therapeutic targets for psoriasis. In this review, we summarized the roles of the *AIM2* gene and *AIM2* inflammasome in pathogenesis and treatment of psoriasis, hopefully providing a better understanding and new insight into the roles of *AIM2* gene and *AIM2* inflammasome in psoriasis.

Keywords: psoriasis, *AIM2*, *AIM2* inflammasome, pathogenesis, treatment

1 INTRODUCTION

Psoriasis is an inflammatory skin disease caused by a combination of environmental incentives, polygenic genetic control, and immune regulation (Branisteanu et al., 2022). The worldwide average prevalence of psoriasis is 2% (Samotij et al., 2020), and the disease is often characterized by recurrence and incurability. It is often accompanied by complex comorbidities such as cardiovascular and autoimmune diseases (Gao et al., 2021), bringing great physical and mental harm to patients, and causing a substantial social-economic burden. The pathogenesis and novel therapies for psoriasis are hot research topics. In the past two decades, many susceptibility genes/loci and epigenetic modification factors of psoriasis have been identified (Nedoszytko et al., 2020). The inflammation-related gene absent in melanoma 2 (*AIM2*) was identified as a susceptibility gene for psoriasis (Zuo et al., 2015), and the function of *AIM2* gene and its role in psoriasis were explored

FIGURE 1 | The assembly and activation of AIM2 inflammasome and subsequently regulatory and trigger pathways in psoriasis. Upon sensing viral DNA, self-derived dsDNA, and cytosolic bacterium, the HIN domain of AIM2 directly recognizes dsDNA in a sequence-independent manner, which triggers the assembly of the AIM2 oligomerization. The PYD domain of AIM2 interacts with the PYD of a recruiting adapter protein ASC, resulting in a high polymer complex AIM2 inflammasome. Inactive procaspases-1 are recruited into AIM2 inflammasome via the CARD-CARD interaction. When the main components of the inflammasome are connecting and the active inflammasome is formed, it directly recruits and cleaves pro-caspase1 into active caspase-1, which proteolytically activates the pro-inflammatory cytokines IL-1 β and IL-18. These inflammatory cytokines directly induce inflammatory responses and participate in the occurrence and development of diseases. The active IL-1 β and IL-18 involve in IL23/Th17 pathway and then induce many kinds of chemokines and inflammatory cytokines, which trigger the development of psoriasis. Interferon-gamma (IFN- γ) promoted the expression of the *AIM2* gene. Epigallocatechin gallate (EGCG), EFLA-945, obovatol, withaferin A (WFA), and RGFP966 are inhibitory effects on AIM2. Prokineticin 2 (PK2), caspase recruitment domain family member 18 (CARD18), aurora kinase A (AURKA), TLR-7, TLR-8, and TLR-9 antagonists are regulators of AIM2 inflammasome signaling pathway.

(Ciężyńska et al., 2021; Liang et al., 2021). In this review, we systemically summarized genetic and epigenetic associations between *AIM2* gene and psoriasis, discussed the roles of *AIM2* gene and AIM2 inflammasome in the pathogenesis of psoriasis, and provided a better understanding of AIM2 inflammasome as a promising therapeutic target for psoriasis.

2 AIM2 GENE AND AIM2 INFLAMMASOME

2.1 AIM2 Gene

DeYoung et al. (1997) reported a novel gene, *AIM2*, also known as *PYHIN4*, located on chromosome 1q23.1-q23.2. The protein AIM2, encoded by the *AIM2* gene is a member of the IFI20X/IFI16 family, consisting of a C-terminal HIN domain and an N-terminal pyrin domain (PYD). RNA sequencing (RNA-seq) of 27 different human tissues showed that the expression level of *AIM2* gene in descending order are: lymph nodes, appendix, and spleen. *AIM2* gene is also expressed at a relatively low level in the skin compared with the top three tissues (Fagerberg et al., 2014). The expression of *AIM2* gene can be promoted by interferon-gamma (IFN- γ) (Tang H. et al., 2021). *AIM2* gene with various functions in the occurrence and development of diseases, the most common function is to initiate the assembly process of the

AIM2 inflammasome. AIM2 response to dsDNA and then induce AIM2-dependent release of IL-18 and IL-1 β , which plays a critical role as a trigger of autoimmune diseases, including psoriasis (Dombrowski et al., 2011), systemic lupus erythematosus (Shin et al., 2019), primary Sjögren's syndrome (Vakrakou et al., 2020). *AIM2* gene plays two-sided roles in tumorigenesis or anti-tumorigenesis in different tumors (Choubey et al., 2000). *AIM2* gene with the tumor-promoting effects in non-small-cell lung cancer (NSCLC) via the inflammasome-dependent manner and regulation of mitochondrial dynamics (Qi et al., 2020). On the contrary, *AIM2* gene is required to restrain the progression of colon cancer through an inflammasome-independent manner, proliferation control of intestinal stem cells, and the regulation of gut microbiota, suggesting that *AIM2* gene plays a protective role in colorectal cancer (Wilson et al., 2015; Zhang Z. et al., 2017).

2.2 AIM2 Inflammasome

In 2009, the composition of the AIM2 inflammasome was reported (Fernandes-Alnemri et al., 2009; Hornung et al., 2009). AIM2 can recognize double-stranded DNA (dsDNA) and interacts with N-terminal PYD. PYD-linked apoptosis-associated speck-like protein (ASC) induces the recruitment of Caspase-1 by the caspase recruitment domain (CARD) of ASC to form the AIM2 inflammasome. AIM2 inflammasome can induce

the maturation and release of inflammatory factors such as IL-1 β and IL-18, triggering an inflammatory response (Wang et al., 2019). Studies over the past decades have shown that AIM2 inflammasome plays a vital role in many kinds of inflammatory diseases, immune diseases, and cancers (Man et al., 2016; Kumari et al., 2020; Zhu H. et al., 2021).

The assembly and activation of AIM2 inflammasome and subsequent inflammatory response was shown in **Figure 1**. The primary role of AIM2 is to initiate the assembly process of the inflammasome. ASC acts as an inflammasome adaptor protein, connecting upstream AIM2 and downstream Caspase-1. Caspase-1 is the effector protein of AIM2 inflammasome, and the activated caspase-1 leads to proteolytic cleavage of IL-1 β and IL-18. The massive release of downstream inflammatory cytokines (IL-1 β and IL-18) directly affects the host's innate immune regulation to infection and injury, induces acute and chronic inflammatory responses, and participates in the occurrence and development of these diseases, such as skin diseases, chronic kidney disease, cardiovascular diseases, neuronal diseases, and diabetes mellitus (Sharma et al., 2019).

3 GENETIC AND EPIGENETIC ASSOCIATIONS BETWEEN AIM2 GENE AND PSORIASIS

3.1 Genetic Associations Between AIM2 Gene and Psoriasis

In the early stage, sequencing results showed that the coding region of AIM2 gene with a high frequency of frameshift and missense mutations in primary high-level microsatellite instability (MSI-H) colon cancers and cell lines (Woerner et al., 2007). In 2015, an exome-wide association study in large-scale individuals was performed to investigate the coding variants in psoriasis. AIM2 gene was firstly identified as a susceptibility gene for psoriasis at the genome-wide level, this gene locates at an important topological position in the gene-gene interaction network. In addition, Zuo et al. (2015) predicted that a variant (rs2276405) in AIM2 gene affects AIM2 protein structure (Glu32Lys). The chemical properties of Glu (the chemical nature of Glu residue is acidic) and Lys (the chemical nature of Lys residue is alkaline) are completely opposite, which may destabilize the alpha-helix motif. Researchers investigated the correlation between the genetic pattern of AIM2 gene polymorphism and the psoriasis phenotype (Li et al., 2016). Genotype and allele distribution of AIM2 gene showed that allele A was the minor allele and G was the risk allele. Genetic pattern analysis showed that the dominant pattern was the best genetic pattern for AIM2 gene polymorphism loci. Compared with the controls, the distribution of the dominant inheritance pattern was higher in psoriasis area and severity index (PASI) score ≤ 20 than that of PASI score > 20 , and family history of negative patients is more significantly different statistically than positive family history.

3.2 Epigenetic Associations Between AIM2 Gene and Psoriasis

Epigenetic associations between AIM2 gene and diseases have also been studied. Hypermethylation of the AIM2 promoter conferred insensitivity to IFN- γ -induced AIM2 expression of MSI-H colon cancer cell lines, demonstrating the inactivation of AIM2 was regulated by epigenetic factors (Woerner et al., 2007). In 2016, an epigenome association study (EWAS) of psoriasis was conducted in the Chinese Han population, and the results showed that three CpG sites (cg17217296, cg17515347, and cg07195224) in the promoter region of AIM2 gene were significantly associated with psoriasis (Li et al., 2016). Assay for transposase-accessible chromatin using sequencing (ATAC-seq) was used to explore the landscape of chromatin accessibility of psoriatic skin tissue (PP) and nonpsoriatic skin tissue (PN) from patients with psoriasis and normal skin tissue (NN) from healthy individuals, the results show that AIM2 gene promoter region was specifically more accessible in PP, and contained a CpG site (cg07195224), which was previously reported to be significantly hypomethylated in psoriasis (Tang L. et al., 2021). In addition, it was observed that the intensity of the promoter-associated peak of AIM2 was negatively correlated with the methylation level of cg07195224 but positively correlated with AIM2 mRNA expression level. Meanwhile, the methylation level of cg07195224 was strongly and negatively associated with AIM2 mRNA expression level (Tang L. et al., 2021). Studies will be needed to explore the correlation between epigenetic regulation and AIM2 gene expression in the future and to further clarify its regulating effect in the pathogenesis of psoriasis.

4 ROLES OF AIM2 GENE AND AIM2 INFLAMMASOME IN THE PATHOGENESIS OF PSORIASIS

4.1 AIM2 Inflammasome Mediated Inflammatory Response Involved in Psoriasis

The roles of AIM2 gene in the pathogenesis of psoriasis have been studied (**Table 1**). AIM2 inflammasome activity may represent a potential trigger for the occurrence and development of inflammatory diseases. Kopfnagel et al. (2011) found that the AIM2 inflammasome is active in human keratinocytes, triggering IL-1 β secretion with an important role in inflammatory processes. In cultured keratinocytes, the expression of AIM2 gene was induced by INF- γ ; cytoplasmic DNA can trigger the release of IL-1 β through the AIM2 inflammasome (Dombrowski et al., 2011). In CD14 $^{+}$ and CD16 $^{+}$ monocyte subsets in the blood of patients with psoriasis, the AIM2 gene expression level was significantly higher than that of the control group, indicating that AIM2 inflammasome exists in the immune cell subsets in the peripheral blood of psoriasis patients in a stimulated state (Verma et al., 2021).

The expression of AIM2 gene in lesional skin from psoriasis patients was explored in several studies (Dombrowski et al., 2011;

TABLE 1 | Roles of *AIM2* gene and AIM2 inflammasome in the pathogenesis of psoriasis.

Studies/Year	Objects	Main findings
Kopfngel et al. (2011)	Keratinocyte	AIM2 inflammasome is active in human keratinocytes and triggers IL-1 β secretion, which represents a potential trigger factor for the development and maintenance of inflammatory skin diseases
Dombrowski et al. (2011)	Skin tissue, Keratinocyte	Abundant cytoplasmic DNA and increased <i>AIM2</i> expression were detected in psoriatic skin lesions; <i>AIM2</i> expression was induced by INF- γ in cultured keratinocytes, and cytoplasmic DNA can trigger the release of IL-1 β through the AIM2 inflammasome
de Koning et al. (2012)	Skin tissue	AIM2 protein expression is significantly upregulated in the psoriatic epidermis. <i>AIM2</i> expression was dynamics in human tissues and primary cells, restricted expression in Langerhans cell and melanocyte of the normal epidermis, but with a strong upregulation in subpopulations of epidermal keratinocytes under inflammatory conditions
Göblös et al. (2016)	Keratinocyte	Gene-specific silencing of <i>CARD18</i> in cells treated with poly (dA:dT) resulted in a significant decrease in <i>AIM2</i> gene expression and significantly reduced <i>Caspase-1</i> mRNA expression, which indicates that <i>CARD18</i> might indeed contribute to the fine-tuning of keratinocyte innate immune processes
Šahmatova et al. (2017)	Skin tissue	<i>AIM2</i> gene was expressed at an increased level in psoriatic skin
Yuan et al. (2020)	Skin tissue	High expression of <i>AIM2</i> gene can be detected in the epidermis of psoriatic skin lesions. Neutrophil extracellular trapping net (NET) may promote the expression of <i>AIM2</i> gene by activating keratinocytes. The secretion of IL-1 β accelerates the inflammatory process of psoriasis
Verma et al. (2021)	Blood	An increased <i>AIM2</i> expression in the CD14 $^{+}$ and CD16 $^{+}$ subsets of patients was observed, suggesting that <i>AIM2</i> exists in a primed state in the immune cell subsets in the peripheral blood of the psoriasis patients
Tang H. et al. (2021)	Skin tissue, Keratinocyte	AURKA promotes the occurrence and development of psoriatic inflammation by blocking autophagy-mediated suppression of the AIM2 inflammasome
Zhao et al. (2022)	Skin tissue	The AIM2 total fluorescence intensity in CD4 $^{+}$ Trm cells in patients with SCLE and localized DLE was higher than in patients with psoriasis. The expression of <i>AIM2</i> gene in skin CD4 $^{+}$ Trm cells can be a significant indicator to distinguish patients with ACLE from those with localized DLE and SCLE.

de Koning et al., 2012; Šahmatova et al., 2017; Yuan et al., 2020). Compared with skin tissues from healthy individuals, abundant cytoplasmic DNA and increased *AIM2* gene expression were detected in psoriatic skin lesions (Dombrowski et al., 2011). Šahmatova et al. (2017) also identified that the *AIM2* gene was expressed at an increased level in psoriatic skin lesions. Yuan et al. (2020) found that the formation of neutrophil extracellular trapping net (NET) structure and the high expression of *AIM2* gene can be detected in the epidermis of skin lesions from psoriasis patients. NET may promote the expression of *AIM2* gene by activating keratinocytes, and the secretion of IL-1 β accelerates the inflammatory process of psoriasis. In addition, the expression of *AIM2* gene is also significantly upregulated in several inflammatory skin disorders, including contact dermatitis, venous ulcers, atopic dermatitis, and experimental wounds (de Koning et al., 2012). The expression of *AIM2* gene was dynamic in human tissues and primary cells, with restricted expression in Langerhans cell and melanocytes of the normal epidermis, but a strong upregulation in subpopulations of epidermal keratinocytes under inflammatory conditions (de Koning et al., 2012).

The IL-23/Th17 axis plays a central role in the development of psoriasis (Hawkes et al., 2017), some biologics (IL-17 antagonists: Secukinumab, Ixekizumab, and Brodalumab; IL-23 antagonists: Risankizumab, Guselkumab, and Tildrakizumab) focus on this signaling pathway have been used for the treatment of moderate-severe psoriasis (Sharma et al., 2022). *AIM2* induces *AIM2*-dependent release of IL-18 and IL-1 β ; furthermore, the active IL-1 β and IL-18 involve in IL23/Th17 pathway and then induce many kinds of chemokines and inflammatory cytokines (Ciążyńska et al., 2021). Taken together, the aforementioned studies indicate that the activation of the AIM2 inflammasome may be a potential trigger for the development of psoriasis, and the inflammatory response mediated by the AIM2 inflammasome

plays an important role in the initial onset and persistence of psoriasis.

4.2 Factors Regulate AIM2 Inflammasome Signaling Pathway in Psoriasis

Recent studies have found that certain factors regulate the AIM2 inflammasome signaling pathway and participate in the pathogenesis of psoriasis, including prokineticin 2 (PK2), caspase recruitment domain family member 18 (*CARD18*), aurora kinase A (*AURKA*), TLR-7, TLR-8, and TLR-9 antagonists.

4.2.1 PK2

PK2 is a psoriasis-specific factor that is highly expressed in mouse and human psoriatic skins, but is not significantly expressed in other autoimmune diseases, such as inflammatory bowel diseases, atherosclerosis, and diabetes; PK2 significantly increases the expression of Caspase-1, and also strongly up-regulates the AIM2 inflammasome signaling pathway in monocytic THP-1 cells, which is engaged by AIM2 to promote the synthesis and secretion of proinflammatory cytokine IL-1 β (He et al., 2016). Thus, PK2 regulates the AIM2 inflammasome signaling pathway involved in the pathogenesis of psoriasis.

4.2.2 CARD18

CARD18 is highly expressed in psoriatic noninvolved epidermis compared to healthy skin epidermis (Szabó et al., 2014). *CARD18* involves AIM2 inflammasome-mediated keratinocyte functions and modifies the inflammatory process in keratinocytes. Silencing of *CARD18* in keratinocyte cells treated with poly (dA:dT) resulted in a significant decrease in *AIM2* gene expression and significantly reduced *Caspase-1* mRNA expression (Göblös et al., 2016), which indicates that

CARD18 may contribute to the fine-tuning of innate immune processes.

4.2.3 AURKA

AURKA is a member of the serine/threonine kinases family, which plays a critical role in the suppression of autophagy (Zhang S. et al., 2017), and is elevated in lesional psoriatic tissue (Liu et al., 2011). A recent study found that AURKA promotes the occurrence and development of psoriatic inflammation by blocking autophagy-mediated suppression of the AIM2 inflammasome (Tang H. et al., 2021).

4.2.4 TLR-7, TLR-8, and TLR-9 Antagonists

Immune modulatory oligonucleotides and small molecular weight compounds, IMO-3100, IMO-8400, and IMO-9200 target TLR-7, TLR-8, and TLR-9, respectively. These are under clinical investigation for their effectiveness in the treatment of psoriasis. Chemical compounds, such as AS-2444697, PF-05387252, PF-05388169, PF-06650833, ML120B, and PHA-408, can inhibit TLR signaling (Gao et al., 2017). Jiang et al. (2013) evaluated an antagonist of TLR-7, TLR-8, and TLR-9 as a therapeutic agent in an IL-23-induced psoriasis model in C57BL/6 mice. Treatment with an antagonist reduced the expression of inflammasome components (including NLRP3, AIM2, and antimicrobial peptides) in the dermis, which indicated that targeting TLR-7, TLR-8, and TLR-9 may provide a method for neutralizing the multiple inflammatory pathways that are involved in psoriasis.

4.3 How Fra-1 Regulates AIM2 and What's the Regulatory Effect in Psoriasis?

Recently, bioinformatics prediction and luciferase reporter assay showed that Fra-1 targeted binding to 363 bp and 57 bp upstream of the AIM2 gene transcription start site (Tang L et al., 2021). Fra-1 is encoded by the *FOSL1* gene and plays a role in cell proliferation and differentiation, gene expression and regulation, and the occurrence and progression of psoriasis (Talotta et al., 2020). *FOSL1* knockdown inhibited IL-22-induced proliferation and enhanced keratinocyte apoptosis, whereas IL-22 stimulation and *FOSL1* overexpression further enhanced keratinocyte proliferation (Meng et al., 2021). The expression of *FOSL1* was significantly increased in lesional psoriatic skin and positively correlated with the PASI score (Sobolev et al., 2011). The aforementioned findings show that the high expression of *FOSL1* in lesional psoriatic skin is one of the markers of the pathological activity of psoriasis and that Fra-1 plays an important role in the pathogenesis of psoriasis. However, Fra-1 needs to be further investigated on how it regulates the expression of AIM2 in psoriasis, which is still unclear.

4.4 The Expression of AIM2 Gene Can Be a Biomarker to Distinguish Different Subtypes of Psoriasis?

The expression level of AIM2 gene in CD4⁺ tissue-resident memory T (CD4⁺ Trm) cells was measured in the patients

with acute cutaneous lupus erythematosus (ACLE), subacute CLE (SCLE), localized discoid lupus erythematosus (localized DLE), psoriasis, and other inflammatory skin diseases (Zhao et al., 2022). The results showed that AIM2 expression in CD4⁺ Trm cells was significantly lower in patients with ACLE than in localized DLE and SCLE. In psoriasis patients, CD4⁺ Trm cells were mainly located in the epidermis of skin lesions. The AIM2 total fluorescence intensity in CD4⁺ Trm cells in patients with SCLE and localized DLE were higher than in patients with psoriasis. Compared to ACLE with localized DLE and/or SCLE, the receiver operating characteristic curve for AIM2 expression in CD4⁺ Trm cells had different sensitivities and specificities at different cutoff values. Therefore, AIM2 expression in skin CD4⁺ Trm cells can be a significant indicator of distinguishing patients with ACLE from those patients with SCLE and localized DLE. Psoriasis is also divided into subtypes with different clinical manifestations, including psoriasis vulgaris, erythrodermic psoriasis, pustular psoriasis, and psoriatic arthritis (Zhu C. et al., 2021). It is worthy to further investigate whether AIM2 expression can be a biomarker to distinguish different subtypes of psoriasis. A valuable study will be carried out in the future to explore this scientific question.

5 AIM2 INFLAMMASOME IS A PROMISING THERAPEUTIC TARGET FOR PSORIASIS

5.1 AIM2 Correlates With Therapeutic Efficacy of Psoriasis

Recent studies have shown that the expression of AIM2 gene can be a biomarker to predict the benefit of therapy in patients with epithelial ovarian cancer (Hsu et al., 2021), melanoma (Fukuda et al., 2021), systemic lupus erythematosus (Yang et al., 2021) and heart failure (Onódi et al., 2021). These studies implicate its potential utility in predicting clinical treatment outcomes. Gong et al. calculated innate immune cell proportion in psoriatic skin by utilizing microarray data, results show that AIM2 gene was negatively associated with resting mast cells but positively associated with activated dendritic cells (Gong and Wang, 2021). Brodalumab and Ustekinumab are used to treat moderate to severe plaque psoriasis, and most patients can get better treatment effects. Interestingly, AIM2 gene was positively associated with the therapeutic efficacy of Brodalumab and negatively associated with Ustekinumab treatment response (Gong and Wang, 2021), which provide novel clues for clinical decisions on treatment for psoriasis. In addition, KEGG analysis shows pathways involving RIG-I-like receptor signaling, NOD-like receptor signaling, toll-like receptor signaling, and cytosolic DNA-sensing pathways, these pathways were significantly enriched and positively correlated with AIM2 gene (Gong and Wang, 2021).

5.2 LL-37 Neutralizes Inflammation Mediated by AIM2 Inflammasome

The antimicrobial peptide LL-37 (also known as cathelicidin antimicrobial peptide, CAMP) is overexpressed in psoriatic lesions and acts as the critical factor that mediates plasmacytoid dendritic cells

(pDCs) activation in psoriasis (Lande et al., 2007). AIM2 inflammasomes activate pro-inflammatory processes and trigger IL-1 β secretion in psoriatic lesions. However, IL-1 β secretion was completely abolished when LL-37 and DNA were delivered together into keratinocytes. This may suggest that LL-37 can translocate into the cytosol of psoriatic keratinocytes and specifically neutralizes cytosolic DNA, thus acting as an inhibitor of AIM2 inflammasome activation (Dombrowski and Schaubert, 2012). Topical treatment with vitamin D analogs decreases inflammation and pro-inflammatory cytokines, but strongly increases cathelicidin's expression (Lebwohl et al., 2004; Peric et al., 2009). However, repeated treatments with narrowband-UVB (NB-UVB) decreased skin inflammation in patients with psoriasis but increased vitamin D serum levels and the expression of cutaneous cathelicidin (Vähävihti et al., 2010). Thus, established therapies targeting the vitamin D pathway reduce inflammatory responses while increasing epidermal antimicrobial peptide expression in psoriatic lesions, the anti-inflammatory effect of LL-37 on the AIM2 inflammasome pathway may account for these observed effects (Reinholz et al., 2012). LL-37 can modulate the pathogenic response to nucleic acids and be helpful for the development of anti-inflammatory therapies.

5.3 Potential AIM2 Inflammasome Inhibitors for Psoriasis Treatment

At present, there are some AIM2 inflammasome inhibitors that have been explored to treat inflammatory diseases, including epigallocatechin gallate (EGCG), EFLA-945, obovatol, withaferin A (WFA), and RGFP966.

5.3.1 EGCG

EGCG is the most abundant main polyphenol component of green tea, and the ally moiety of catechins possesses the most biological activities, including angiogenesis and anti-inflammatory effects (Kondo et al., 2002). The structure of EGCG and related information are shown in **Supplementary Figure S1**. EGCG inhibits the transfection of NF- κ B and AP-1 to downregulate the expression of reactive oxygen species (ROS) and reactive nitrogen species (RNS) and decreases the production of inflammatory factors (Nagai et al., 2002). Studies have shown that EGCG attenuates AIM2-induced IL-1 β secretion by inhibiting inflammasome IFN- γ secretion and dA:dT-induced ASC oligomerization in neonatal human epidermal keratinocytes (Yun et al., 2015).

5.3.2 EFLA-945

EFLA-945 is an extract from red grapevine leaf in traditional medicine in Japan (Rabe et al., 2011) and over-the-counter drugs in Europe and Japan (Hoshino et al., 2018) for its anti-inflammatory properties and circulatory benefits. Resveratrol (**Supplementary Figure S2**) and peonidin 3-O-glucoside (**Supplementary Figure S3**) are the major phytochemicals of EFLA 945. Study results showed that EFLA-945 could limit the entry of DNA into THP-1-derived macrophages, thereby inhibiting cytoplasmic DNA-dependent ASC and activation of the AIM2 inflammasome. Resveratrol and peonidin 3-O-glucoside are two major phytochemicals of EFL-945 that mediate this inhibition (Chung et al., 2020). Furthermore,

EFLA-945 attenuated the associated pro-inflammatory response in localized skin lesions of an imiquimod-induced psoriasis-like mouse model, indicating that EFLA-945 may be beneficial for the treatment of psoriasis.

5.3.3 Obovatol

Obovatol (**Supplementary Figure S4**), a bisphenol chemical originating from *Magnolia obovata*, affects the AIM2 inflammasome by inhibiting the formation of ASC pyroptosome and the generation of mitochondrial ROS. Furthermore, obovatol has been used as a traditional treatment for inflammatory diseases (Kim et al., 2019) and neuroinflammation (Ock et al., 2010). Furthermore, obovatol disrupted inflammasome activation's initiation step, inhibited the transcription of inflammatory cytokines, and decreased serum IL-1 β elevation in response to sodium urate crystals in mice (Kim et al., 2019). Whether obovatol has a therapeutic effect on psoriasis will be further studied.

5.3.4 WFA

WFA is an extract from the medicinal plant *Withania somnifera* and has various biological activities, including acting as an anti-inflammatory, angiogenesis, and anticancer (Mohan et al., 2004). The structure of EGCG and related information are shown in **Supplementary Figure S5**. Studies show that WFA regulates AIM2 inflammasome and Caspase-1 in THP-1 polarized macrophages; however, WFA treatment of M2 macrophages inhibits TGF- β compared with M1 secretion (Ngoungoure and Owona, 2019). Currently, further research is needed to determine whether WFA can affect the occurrence and progression of psoriasis by inhabiting the AIM2 inflammasome pathway.

5.3.5 RGFP966

Histone deacetylases 3 (HDAC3) modulates the acetylation of histone and non-histone proteins. RGFP966 (**Supplementary Figure S6**) is a selective inhibitor of HDAC3 (Zhang et al., 2020). Specifically, RGFP966 regulates the inflammatory process in stroke (Chen et al., 2012) and brain damage (Zhang et al., 2020). Lipopolysaccharide (LPS) stimulation caused time-dependent increases of HDAC3 and AIM2 inflammasome in primary cultured microglia. AIM2 gene was spatiotemporally regulated by RGFP966, which was confirmed in an experimental mouse stroke model. RGFP966 can enhance STAT1 acetylation and decrease STAT1 phosphorylation, which may partially explain the negative regulatory effect of AIM2 gene by RGFP966 (Zhang et al., 2020). This study indicated that RGFP966 alleviated the inflammatory process by regulating the AIM2 inflammasome. The further therapeutic effects of RGFP966 on psoriasis by regulating the AIM2 inflammasome will be investigated in the future.

6 THE DISADVANTAGES OF TARGETING AIM2 GENE AS A POTENTIAL THERAPEUTIC TARGET

AIM2 gene act as a double-edged sword in the pathogenesis of some autoimmune diseases and cancers. The increased and decreased expression of AIM2 gene with different roles in the development

of different diseases. *AIM2* gene plays the tumor-suppressive role in HPV-infected cervical cancer (So et al., 2018), breast cancer (Yoon et al., 2015), squamous cell carcinoma (Farshchian et al., 2017); while *AIM2* gene is regarded as a protective factor in melanoma (DeYoung et al., 1997; de Koning et al., 2014) and colorectal cancer (Wilson et al., 2015; Zhang Z. et al., 2017). Intriguingly, *AIM2* gene with two contrasting roles in different models or different disease stages of hepatocellular carcinoma (Martínez-Cardona et al., 2018; Shi et al., 2019). *AIM2* gene as a therapeutic target may with different effects on different diseases, therefore we should consider the advantages and disadvantages of targeting *AIM2* gene. For instance, when we use *AIM2* inflammasome inhibitors or drugs to treat psoriatic patients also with cancer, in the future, we need to pay attention to its impact on cancer. Taken together, the advantages and disadvantages of targeting *AIM2* gene should be considered at the same time.

7 CONCLUSION AND PERSPECTIVES

In this review, we provided an overview of the research progress on the effect and role of *AIM2* gene and *AIM2* inflammasome in psoriasis. We hope this provides further potential therapeutic targets for psoriasis. Although some potential inhibitors of the *AIM2* inflammasome were explored, no *AIM2* inflammasome target drug has been used in the clinical treatment of psoriasis. Therefore, further researches need to focus on the development of new drugs for psoriasis.

A major goal of genetics research is to elucidate mechanisms explaining how genetic variation contributes to phenotypic variation. The genetic variants identified in genome-wide association studies (GWASs) generally explain only a small proportion of heritability of phenotypic traits, the so-called missing heritability problem. Recent evidence suggests that additional common variants beyond lead GWAS variants contribute to phenotypic variation; however, their mechanistic underpinnings generally remain unexplored. Herein, we undertake a study of haplotype-specific mechanisms of gene regulation at 8p23.1 in the human genome, a region associated with a number of complex diseases. The *FAM167A-BLK* locus in this region has been consistently found in the genome-wide association studies (GWASs) of systemic lupus erythematosus (SLE) in all major ancestries. Our haplotype-specific chromatin interaction (Hi-C) experiments, allele-specific enhancer activity measurements, genetic analyses, and epigenome editing experiments revealed that: 1) haplotype-specific long-range chromatin interactions are prevalent in 8p23.1; 2) *BLK* promoter and *cis*-regulatory elements cooperatively interact with haplotype-specificity; 3) genetic variants at distal regulatory elements are allele-specific modifiers of the promoter variants at *FAM167A-BLK*; 4) the *BLK* promoter interacts with and, as an enhancer-like promoter, regulates *FAM167A* expression and 5) local allele-specific enhancer activities are influenced by global haplotype structure due to chromatin looping. Although systemic lupus erythematosus causal variants at the *FAM167A-BLK* locus are thought to reside in the *BLK* promoter region, our results reveal that genetic variants at distal regulatory elements modulate promoter activity, changing *BLK* and *FAM167A* gene expression and disease risk. Our results suggest that global haplotype-specific 3-dimensional chromatin looping architecture has a strong influence on local allelic *BLK* and *FAM167A* gene expression, providing mechanistic details for how regional variants controlling the *BLK* promoter may influence disease risk.

gene regulation, enhancer, enhancer-like promoter, genetic interaction, missing heritability, *BLK*, systemic lupus erythematosus (SLE), *FAM167A*

Introduction

Contemporary genetics research aims to understand mechanisms of how variation in DNA sequence underlies phenotypic variation in normal and disease states. Genome-wide association studies (GWASs) have identified thousands of genetic loci associated with over 4,000 phenotypes (www.ebi.ac.uk/gwas/). However, genetic variants identified in GWAS studies explain only a modest fraction of total genetic risk in complex diseases, leading to the so-called missing heritability problem (Manolio et al., 2009). Recent evidence suggests that additional common variants beyond the lead GWAS single nucleotide polymorphisms (SNPs) contribute to disease risk (Gusev et al., 2013; Corradin et al., 2014; Gusev et al., 2014; Corradin et al., 2016; Boyle et al., 2017). However, mechanistic underpinnings of how additional genetic variants contribute to disease risk have not been thoroughly investigated for the vast majority of disease risk loci. Some suggest that a proper account of genetic interactions may help solve the missing heritability problem (Zuk et al., 2012). GWAS associations most often occur in non-coding regions of the genome, presumably at gene regulatory elements (GREs) (Hindorff et al., 2009), suggesting that additional risk variants will be found in GREs as well.

Transcriptional regulation is a complex process involving 3-dimensional (3D) chromatin interactions of GREs (Li et al., 2018). Combinations of genetic polymorphisms affecting various components in this process may thus alter gene expression and contribute to disease risk. The importance of 3D genome architecture for gene regulation in normal and disease states has been increasingly appreciated and is clearly a tremendous source for important new knowledge (Babu and Fullwood, 2015; Krijger and de Laat, 2016). The techniques based on chromosome conformation capture have emerged as methods of choice for mapping the 3D structure of the human genome (de Wit and de Laat, 2012). In particular, capture Hi-C, a high-throughput method to identify chromatin interactions in large genomic regions, has been used to determine high-resolution 3D genome structures at some disease-associated loci (Dryden et al., 2014; Jäger et al., 2015).

In order to investigate the role of haplotype-specific 3D chromatin structure in allelic gene expression, we have chosen the 8p23.1 region on human chromosome 8.8p23.1 contains associations with a number of complex diseases and the largest (4.5 Mb) known common DNA inversion region in humans (Salm et al., 2012; Namjou et al., 2014). The *FAM167A-BLK* locus in this region, for example, has been consistently found to be associated with systemic lupus erythematosus (SLE) GWASs in all major ancestries (International Consortium for Systemic Lupus Erythematosus Genetics (SLEGEN) et al., 2008; Hom

et al., 2008; Ito et al., 2009; Suarez-Gestal et al., 2009; Sánchez et al., 2011; Castillejo-López et al., 2012; Delgado-Vega et al., 2012; Guthridge et al., 2014).

Associations with the *BLK* locus have also been identified in rheumatoid arthritis (RA), systemic sclerosis (SSc), Sjögren's syndrome (SjS), Kawasaki's disease (KD), antiphospholipid syndrome (APS) and maturity-onset diabetes of the young (MODY), thus justifying a focused mechanistic study of this locus (Hom et al., 2008; Borowiec et al., 2009; Yin et al., 2009; Gourh et al., 2010; Tsuchiya et al., 2010; Lessard et al., 2013). *BLK* is a signal transduction molecule that is important for sustaining the inflammatory response, including autoimmune responses. *BLK* probably plays an important role in early B cell development; thus, its dysregulation may result in a breakdown of peripheral self-tolerance during B cell development (Nashi et al., 2010; Simpfendorfer et al., 2012).

SLE patients have lower levels of the *BLK* gene product, a finding that is correlated with the risk alleles at the *FAM167A-BLK* locus (Hom et al., 2008). The strongest SLE association signal at the *BLK* locus is from the promoter SNP rs13277113 (Hom et al., 2008). The trans-population mapping and sequencing strategy was used in (Guthridge et al., 2014) to identify two putative SLE causal variants, rs922483 and rs1382568, at the *BLK* promoter region. The data available have led to a general consensus in the SLE genetics research community that causal variants at *FAM167A-BLK* are very likely to be in the *BLK* promoter region.

Our haplotype-specific chromatin interaction high-resolution Hi-C experiments, allele-specific enhancer activity H3K27ac measurements, genetic analyses, and epigenome editing experiments revealed that 1) haplotype-specific long-range chromatin interactions in 8p23.1 are prevalent, 2) *BLK* promoter and *cis*-regulatory elements cooperatively and haplotype-specifically interact, 3) *BLK* promoter interacts with and, as an enhancer-like promoter, regulates *FAM167A* expression, and 4) genetic variants at distal regulatory elements are allele-specific genetic modifiers of the promoter variants at *FAM167A-BLK*.

Our findings suggest a 'risk dosage' model whereby disease risk alleles at multiple regulatory elements at *BLK* locus synergistically decrease gene expression, thereby increasing SLE disease risk. Although SLE causal genetic variants are thought to reside in the *BLK* promoter region, we show that haplotype-specific distal genetic variants at regulatory elements modulate the effects of *BLK* promoter variants on gene expression and disease risk. More generally, our results suggest that global haplotype-specific 3-dimensional chromatin looping architecture may have a strong influence on local allelic gene expression and disease risk in SLE, as

well as in other complex diseases, and provide a model for a risk dosage approach to regulatory susceptibility loci, in general.

Results

Haplotype-specific chromatin looping

Long-range chromatin interactions are important for transcriptional regulation of genes (Chepelev et al., 2012; Krijger and de Laat, 2016). We suspected that causal genetic variants at *FAM167A-BLK* dysregulate normal gene expression by altering chromatin looping interactions. We thus hypothesized that in B cell lines heterozygous for SLE-associated SNPs in the 8p23.1 region, 3D chromatin structures of risk and non-risk haplotypes would differ. To test this hypothesis, we prepared capture Hi-C libraries from two 1,000 Genomes EBV-infected lymphoblastoid cell lines (LCLs), NA07000 and NA07056, both heterozygous for the SLE-associated SNP rs922483 (Guthridge et al., 2014), located in the promoter of *BLK*.

Capture Hi-C is a high-throughput, cost-effective method to identify long-range 3D chromatin interactions in a subset of the genome (Dryden et al., 2014) (see Materials and Methods, and Figure 1). We identified the haplotype-resolved 3D structure of a 3 Mb region in 8p23.1 at 5 kb resolution. At the false discovery rate (FDR) of 5%, we have identified 780 and 791 differential haplotype-specific chromatin interactions in NA07000 and NA07056 cell lines, respectively (Supplementary Tables S1, S2). Approximately half of these interactions are stronger and half of the interactions are weaker on SLE risk haplotype than on non-risk haplotype. Among the differential haplotype-specific

interactions in 8p23.1, some are in the vicinity of the *BLK* locus (Figure 2).

In the ENCODE Project (encodeproject.org) data, several extended regions at the *BLK* locus show enrichment for the H3K27ac histone modification mark in LCLs and primary B cells. (We designate these regions E1, E2, E3, and P in Figure 2). The H3K27ac mark is thought to be associated with active enhancers in the genome (Creyghton et al., 2010). Our haplotype-specific Hi-C data described below strongly suggest that these regions positively regulate *BLK* expression. Our capture Hi-C data show that enhancer E3, located more than 50 kb away from the *BLK* transcription start site, interacts with the promoter in a haplotype-specific manner. Consistent with lower expression of *BLK* on the SLE risk haplotype, P-E3 interaction frequency on the SLE risk haplotype is lower than on the non-risk haplotype (Figure 2). It has been known for some time that enhancers can interact with other enhancers in the 3D genome (Chepelev et al., 2012). We found that enhancers also interact with each other in a haplotype-specific way (Figure 2), again with weaker interactions on the risk haplotype. These results are consistent with long-range chromatin interactions between enhancers playing a role in co-operatively enhancing *BLK* expression.

Intriguingly, we found that the interaction of the *BLK* promoter with a distal REST binding site located 115 kb away (Figure 2) is stronger on SLE risk haplotype, consistent with the repressive role of REST (repressor element 1-silencing transcription factor) (Ooi and Wood, 2007) and lower expression level of *BLK* gene on SLE risk haplotype.

Function of the *FAM167A* gene located 27 kb upstream of *BLK* has recently been shown to be an activator of the non-canonical activation pathway of NFκB, which is potentially important for mechanisms of the inflammatory phenotypes

with genetic associations at this locus (Mentlein et al., 2018; Yang et al., 2022). We, therefore, retain *FAM167A* as an SLE candidate gene, acknowledging the existing circumstantial evidence supporting *BLK* as a participant in the mechanism altering disease risk. *FAM167A* is upregulated 8-fold upon B cell receptor stimulation (publicly available RNA-seq data in GEO GSE61608). Further, RA-associated variants exhibit high LD ($r^2 > 0.8$) with a B cell selective cis-eQTL for *FAM167A* expression identified in a cohort of early RA patients (Thalayasingam et al., 2018). The haplotype-specific expression patterns of these two genes are anti-correlated: *BLK* is less expressed on the SLE risk haplotype than on the non-risk haplotype, whereas *FAM167A* is more expressed on the risk haplotype than on the non-risk haplotype (Figure 3B) (Hom et al., 2008). Our capture Hi-C data revealed that *FAM167A* and *BLK* promoters interact, with the interaction being stronger on risk-haplotype in NA07000, but not in NA07056 cells (Figures 2,3A). Our model is summarized in Figure 3B. It has previously been proposed that promoters can regulate other promoters via chromatin looping interaction (Xu et al., 2011). Many promoter-promoter chromatin interactions have previously been identified genome-wide (Chepelev et al., 2012; Li et al., 2012). Promoters with enhancer activity, the so-called enhancer-like promoters, have been described recently (Dao et al., 2017; Dao and Spicuglia,

2018). That the promoters of *FAM167A* and *BLK* genes may functionally interact in this manner is consistent with these data and remains an intriguing possibility.

Since SLE causal variants at *FAM167A-BLK* are very likely to be in the *BLK* promoter region (see discussion in Introduction) and given our findings above, we hypothesized that these variants may have functional effects on modulating *FAM167A* expression, and on disease risk, via haplotype-specific chromatin interaction between promoters of *BLK* and *FAM167A*. We thus sought to perturb *BLK* expression and measure changes in *FAM167A* expression.

We infected NA07000 LCL cells, in which *BLK* and *FAM167A* are expressed, with a lentivirus to express a dCas9-KRAB fusion protein for targeted gene repression (see Figure 4A) (Thakore et al., 2015). When localized to genomic DNA, KRAB recruits a heterochromatin-forming complex that causes histone methylation and deacetylation. We targeted dCas9-KRAB to the E3 enhancer region in NA07000 cells by transfection of plasmids expressing appropriate guide RNAs (gRNAs) (Supplementary Tables S3,S4). The *BLK* expression was down-regulated by ~19% and *FAM167A* expression was up-regulated by ~37% as a consequence of the targeting of dCas9-KRAB to the E3 enhancer region (Figures 4B,C).

FIGURE 3

Haplotype-specific *FAM167A*-*BLK* promoter-promoter interactions in NA07000 cells. **(A)** *FAM167A*-*BLK* interaction is stronger on SLE risk haplotype. Shown is a heatmap view of Hi-C chromatin interaction frequencies on non-risk and risk haplotypes, darker purple representing higher interaction frequencies. Each square represents an interaction between two 5 kb genomic regions located at the diagonal extension intersecting the horizontal line. The circled squares represent interactions between two 5 kb regions located where blue and orange vertical bands meet the horizontal line (at *FAM167A* and *BLK* promoters). **(B)** *BLK* and *FAM167A* have anti-correlated expression patterns. *BLK* is less and *FAM167A* is more expressed on the risk (lower panel) than on the non-risk (upper panel) haplotype. Shown also is a putatively SLE causal promoter SNP rs922483 with its non-risk (C) and risk (T) alleles.

The up-regulation of *FAM167A* may be a direct or an indirect consequence of perturbation of chromatin state at enhancer E3 by KRAB. In order to distinguish between these two possibilities, we chose K562 cells to perform epigenome editing to activate enhancer E3. The *BLK* and *FAM167A* genes are not expressed beyond the basal level in K562 cells and the *BLK* enhancers are not active since they have no H3K27ac signal in K562 cells (Supplementary Figure S1). We infected K562 cells with a lentivirus to express a dCas9-p300 fusion protein (Hilton et al., 2015; Klann et al., 2017) (see Figure 6A). The p300 is a histone acetyltransferase that acetylates H3K27. While *BLK* is strongly up-regulated by targeting of dCas9-p300 to enhancer E3 in K562 (Figure 4B), *FAM167A* expression did not change (Figure 4C). This suggests that the E3 region is not directly involved in regulating *FAM167A* expression. More likely, the effect of targeting dCas9-KRAB to E3 on *FAM167A* expression is indirect and is mediated by increased long-range chromatin interaction frequency between promoters of *BLK* and *FAM167A*, brought about by down-regulation of *BLK* expression (see the model in Figure 4D). We hypothesize that upon down-regulation of *BLK* transcription, an enhancer-like activity of *BLK* promoter goes up, which leads to its long-range chromatin interaction with *FAM167A* promoter and up-regulation of *FAM167A* expression.

Haplotype-specific enhancer activity

Our Hi-C data revealed haplotype-specific interactions of enhancers with the *BLK* promoter. We thus hypothesized that enhancer activities should be stronger on the SLE non-risk haplotype. We cloned NA07056 risk and non-risk haplotype enhancer sequences into luciferase reporter vectors and transfected LCLs with these constructs. The reporter assay data show that the activity of enhancer E3 is haplotype-specific, and is less active on the SLE risk haplotype (Figure 5A). This result is consistent with the chromatin interaction analysis above. Reporter experiments revealed that enhancer activity of non-risk E3 sequence is ~1.5 times higher than the activity of risk E3 sequence (Figure 5A). Intriguingly, our allele-specific ChIP-qPCR experiments showed that the H3K27ac signal at E3 enhancer on non-risk haplotype is ~8.5 times higher than on the risk haplotype (Figure 5B). We hypothesize that the allelic differences in regulatory element activities are determined not only by local DNA sequence variations at the element but also by allelic differences at distal sites, due to the amplification effect of chromatin looping interactions in the 3D chromatin context. We have tested our hypothesis for one enhancer (E3) in one cell line in our experiments, suspecting that this is a more general phenomenon and that analogous findings would hold true also at many other regulatory regions.

FIGURE 4

dCas9-KRAB targeting reveals regulation of *FAM167A* expression by *BLK* promoter region. (A) Schematics of epigenome editing (repressor KRAB) experiment in NA07000 LCL cell line. (B) Targeting of dCas9-KRAB to enhancer E3 in NA07000 cells results in down-regulation of *BLK*. Targeting of dCas9-p300 to enhancer E3 in K562 cells results in ~400 folds up-regulation of *BLK* (two left-most bars in the main figure and the inset for an expanded view). For the schematics of dCas9-p300 experiments, see Figure 6A. (C) Targeting of dCas9-KRAB to enhancer E3 in NA07000 cells results in up-regulation of *FAM167A* expression. (D) A model to explain data in (B–C). The dotted arrow with the red ‘STOP’ sign symbolizes the following finding from (C) (two left-most small bars grouped as ‘K562-dCas9-p300’ cell line): targeting of activator p300 to enhancer E3 in K562 cells did not result in up-regulation of *FAM167A* expression. This suggests that E3 does not directly regulate *FAM167A* expression. Rather, the effect of repressing E3 on *FAM167A* expression is mediated by *FAM167A*-*BLK* promoter-promoter interaction (see Figures 2,3). In (B,C), the *BLK* and *FAM167A* expression values shown are relative to their expression levels in K562-dCas9-p300 cells transfected with empty vector (EV) (the left-most bars in (B) and (C) have values identically equal to 1). EV, empty vector.

Epigenome editing reveals participating elements in *BLK* regulation

Our Hi-C data revealed haplotype-specific chromatin looping interactions between enhancers and the promoter at the *BLK* locus. Based on these findings, we hypothesize that enhancers and promoter pairs synergistically regulate *BLK* expression. For the lack of baseline *BLK* expression and the absence of an H3K27ac signal at the enhancers (Supplementary Figure S1), we again chose K562 cells, here performing epigenome editing to activate *BLK* expression and test the hypothesis. We infected K562 cells with a lentivirus to express a dCas9-p300 fusion protein (Hilton et al., 2015; Klann et al., 2017) (see Figure 6A). The p300 is a histone acetyltransferase that acetylates H3K27. We targeted dCas9-p300 to E2, E3 and promoter regions singly and in combinations in K562 cells by transfection of plasmids expressing appropriate guide RNAs

(gRNAs) (Supplementary Tables S3,S4). Strong synergistic activation of the *BLK* gene (500 to 900-fold increases) was observed for E2-E3 and E3-promoter targeting by p300 (Figures 6B,C), thereby confirming the regulatory role of this genome region for *BLK*.

Multiple genetic variants contribute to variance in *BLK* expression

Since gene regulation is a complex process involving interactions of multiple regulatory regions and protein complexes, we reasoned that many genetic variants may contribute to variance in *BLK* expression. We analyzed gene expression and genotype data from 344 European individuals (Lappalainen et al., 2013), henceforth denoted as dataset D344, using the genetic relationship matrix approach as implemented

**FIGURE 5**

Haplotype-specific enhancer activity. **(A)** Allelic luciferase activities of enhancers in NA07056 cells. N: SLE non-risk haplotype sequence, R: SLE risk haplotype sequence. Non-risk enhancer E3 sequence reporter activity is ~1.5x higher than that of risk sequence. **(B)** Allele-specific ChIP-qPCR at E3 enhancer in NA07056 cells in which the SNP rs2244931 is heterozygous. Non-risk to risk enhancer activity ratio in native chromatin context is significantly higher ~8.5x (calculated as normalized ratio $(N/R)_{\text{ChIP}}/(N/R)_{\text{Input}}$; See Materials and Methods for details), presumably due to “amplification of E3 enhancer activity due to long-range chromatin interactions” effect (see haplotype-specific E1-E3 and E2-E3 interactions in Figure 2).

in GCTA software (Yang et al., 2010) to estimate *BLK* gene expression variance explained by various sets of SNPs. The SLE-associated proxy rs922483 alone explained around 25% of expression variance. Inclusion of all SNPs in putative regulatory regions of *BLK*, as defined by the H3K27ac epigenetic mark and REST binding region (see Figure 2; Supplementary Table S7), increased the variance explained to 44%, supporting the contention that multiple SNPs at the *BLK* locus explain variance in gene expression.

Enhancer haplotypes modulate *BLK* expression

Given our findings, we sought to find more direct evidence for the causal effects of enhancer haplotypes on *BLK* expression. To this end, we derived an SLE credible set of 11 SNPs, termed BLK-CS-11, from existing genotype data (see Materials and Methods, and Supplementary Table S5) and used phased genotype data for individuals of European ancestry from the 1000 Genomes Project (1000genomes.org) to extract haplotype sequences of the *BLK* locus. We then computed frequencies of different promoter haplotype sequences in the dataset.

The frequency of promoter risk haplotype CCCCTAAACA (based on 11 SNPs in BLK-CS-11) (Figure 7A), which we denote henceforth as prom-R, is 24%. The most frequent non-risk haplotype TGTACCGGGTG, which we denote as prom-N, is present at 72%. In subsequent analyses, we will focus on these two main haplotypes, which together account for 96% of all European haplotypes. The rows in the heatmap plot in Figure 7A correspond to the haplotypes, with the rows labeled as “Risk”

representing promoter “risk” haplotypes and the rows labeled as ‘Non-risk’ representing promoter “non-risk” haplotypes, respectively.

We next asked, conditioned on the promoter haplotype, what are the local haplotype sequences at candidate enhancer E1, E2, and E3 regions defined by islands of H3K27ac enrichment? The promoter and enhancer haplotype sequences are displayed in Figure 7A. The haplotypes are grouped based on promoter haplotype: risk for prom-R (upper block) and non-risk for prom-N (lower block). We conditioned on the promoter haplotype prom-R and counted different local haplotypes at E1, E2, and E3. The most frequent E1, E2, and E3 haplotypes, conditioned on prom-R haplotype, denoted as E1-R, E2-R, and E3-R, respectively, are present in 87%, 85%, and 54% of all prom-R haplotypes, respectively. Our choice of the label “R” in the naming of these enhancer haplotypes may seem arbitrary; the use of this label emphasizes the effect of these haplotypes on *BLK* expression and disease risk discussed below. Interestingly, the haplotype combination (prom-R, E1-R, E2-R, E3-R), which can be seen in the upper dotted box in Figure 7A, is frequent and constitutes 48% of all promoter-E1-E2-E3 haplotypes conditioned on prom-R and 11% of all European subject chromosomes.

Similarly, the most frequent E1, E2, and E3 haplotypes, conditioned on prom-N haplotype, denoted as E1-N, E2-N, and E3-N, respectively, are present in 25%, 70%, and 50% of all prom-N haplotypes, respectively. Interestingly, the haplotype combination (prom-N, E1-N, E2-N, E3-N), which can be seen in the lower dotted box in Figure 7A, is frequent and constitutes 24% of all promoter-E1-E2-E3 haplotypes conditioned on prom-N. All other alternative local haplotypes at E1, E2, and E3,

different from N and R haplotypes defined above, are denoted by E1-A, E2-A, and E3-A, respectively. We will use simplified notation, such as RNRN for (prom-R, E1-N, E2-R, E3-N) haplotype, subsequently.

We next asked: how does the *BLK* mRNA level depend on different haplotype combinations at the promoter, E1, E2, and E3? To answer, we used RNA-seq expression data from dataset D344 [gene expression from 344 European individuals (Lappalainen et al., 2013)]. We have defined two groups of samples based on their multilocus genotypes (i.e., pairs of haplotypes in each individual) NNNN/NNNN and RRRR/RRRR. We have also defined two more groups of samples based only on promoter multilocus genotypes prom-N/prom-N and prom-R/prom-R, denoted N/N and R/R, respectively. The boxplot of expression levels in these 4 groups is shown in Figure 7B. There is a clear “risk-dosage” dependent decrease in *BLK* expression level in these data, with the contributions of “risk” from both the promoter and enhancer variants. Analyses for *BLK* promoter-enhancer pairs, shown in Figures 7C–E, support a risk-dosage model according to which the risk status of local haplotypes at cis-regulatory regions cumulatively contributes to a reduction in *BLK* expression. As defined earlier, alternative local haplotypes at E1, E2, and E3, different from N and R haplotypes, are denoted as “A”. By replacing N’s with A’s in the analyses, we found almost identical results as above, suggesting that A and N enhancer haplotypes have similar effects on *BLK* expression (data not shown).

Genetic interactions at *FAM167A-BLK* locus are enriched in regulatory regions

We have provided evidence supporting the hypothesis that enhancer haplotypes can influence *BLK* expression by acting as genetic modifiers of promoter haplotypes. However, we excluded from our analysis genetic variants outside of gene regulatory elements/regions (GREs). What is the contribution of the non-GRE variants to *BLK* expression and do these variants interact? To address this question, we analyzed data D344 [gene expression data from 344 European individuals (Lappalainen et al., 2013)]. For each pair of SNPs, we fitted a linear ($y = b_0 + b_1x_1 + b_2x_2$) and an interaction ($y = b_0 + b_1x_1 + b_2x_2 + b_{12}x_1x_2$) model to *BLK* expression and genotype data (y denotes expression level and x_1 , x_2 denote 0/1/2 coded genotypes of the two SNPs under consideration). The log-likelihood ratio test was used to determine statistically significant genetic interactions. If our hypothesis is true, then the genetic interactions are predicted to be predominantly between SNPs located at GREs. However, SNPs at the *BLK* locus are in high linkage disequilibrium with each other; therefore, the statistically identified genetic

interactions may not necessarily be between genetic variants that causally influence *BLK* expression.

In order to perform an unbiased test of genetic interaction enrichment at regulatory regions, we separated genetically interacting SNP pairs identified by our statistical analysis into two groups: 1) SNPs pairs that are in two different gene regulatory regions (GRE-GRE group) and 2) SNP pairs with at least one SNP not in a regulatory region (non-GRE-GRE group). The genomic coordinates of gene regulatory regions and details of the analysis are given in Materials and Methods. A ranked list of $-\log_{10}(p\text{-value})$ of genetic interactions in each group was generated. Quantile-quantile analysis revealed that genetic interactions in the GRE-GRE group are more significant than in the non-GRE-GRE group ($p\text{-value} = 0.0003$) (Figure 8), thereby demonstrating enrichment of genetic interactions between gene regulatory elements.

Materials and methods

Cell culture

K562 cells were obtained from the American Tissue Collection Center (ATCC). NA07056 and NA07000 LCLs were obtained from the Coriell Institute for Medical Research cell repository. K562 cells were maintained in Iscove’s Modified Dulbecco’s Medium supplemented with 10% FBS and 1% penicillin-streptomycin. LCLs were maintained in RPMI medium supplemented with 10% FBS and 1% penicillin-streptomycin. K562 and LCLs were grown at 37°C in 5% CO₂.

Capture Hi-C experiments

Capture Hi-C libraries were prepared according to the protocol described in (Jäger et al., 2015). The protocol consists of two parts: Hi-C library preparation and target enrichment (Figure 1A). A SureSelect Custom Target Enrichment Library covering a 3 Mb region in the 8p23.1 (hg19 coordinates: chr8:8,190,000–11,838,000) was designed using eArray software (Agilent). Hi-C library preparation, comprising chromatin fixation, HindIII digestion, biotin labelling, ligation, and crosslink reversal was performed as described in (Rao et al., 2014) with minor modifications described in (Jäger et al., 2015). Target enrichment was performed according to the SureSelect protocol (Agilent) with minor modifications described in (Jäger et al., 2015). We have prepared 10 capture Hi-C libraries from 5 independent batches of NA07000 cells and 4 capture Hi-C libraries from 2 independent batches of NA07056 cells. The libraries were sequenced on Illumina HiSeq 2,500 system, producing 461 million and 206 million

paired-end 2×125 bp reads for NA07000 and NA07056, respectively.

Allele-specific luciferase assay

We amplified ~2 kb DNA fragments located in the E1, E2, and E3 enhancer regions (see Figure 2; the hg19 coordinates of the fragments are chr8:1,1,391,971–11,391,971, chr8:11,394,297–11,396,127 and chr8:11,402,768–11,404,795, respectively) from the genomic DNA of NA07056 lymphoblastoid cells using PCR with primers listed in Supplementary Table S6. The PCR products were cloned into pCR2.1-TOPO vector (catalog #K4500-01, Invitrogen) and sub-cloned into pGL4 luciferase reporter vectors (catalog #E6651, Promega). The bacterial cells were then transformed, and single-cell colonies were isolated and Sanger-sequenced to identify SLE risk and non-risk clones using phased haplotype data from the 1000 Genomes Project.

An internal control reporter vector containing Renilla luciferase was simultaneously transfected with our experimental vectors as a control for assay-to-assay variability. One microgram of each vector was transfected into the NA07056 (10^6 cells per sample in triplicate). Cells were then incubated at 37°C for 24 h. Luciferase activity was measured with the Dual-Luciferase Reporter Assay System (catalog #E1960, Promega). Luciferase activity was normalized through the division of *BLK* risk or non-risk construct reporter activity by the reporter activity of the pRL-TK-Renilla luciferase construct. The mean and standard error of measurement were calculated on the basis of the normalized luciferase activities. The one-sided Student's t-test was used to compare the N and R groups in Figure 5A.

Allele-specific H3K27ac ChIP-qPCR

Three independent chromatin immunoprecipitation (ChIP) experiments in NA07056 cells were carried out using antibodies against H3K27ac (catalog #C15410196, pAb-196-050, Diagenode) following a standard protocol. Enhancer E3 (see Figure 2) SNP rs2244931 is heterozygous in NA07056 (C/G, where G is on the SLE risk haplotype). Allelic H3K27ac levels at rs2244931 were quantified using TaqMan custom SNP Genotyping Assay, TaqMan Genotyping Master Mix (catalog # 4,371,353, Applied Biosystems), and input/ChIP DNA. The allelic ratios in the ChIP and input DNA were determined by fitting log2 transformed VIC/FAM ratios to a standard curve constructed from DNA with known rs2244931 allelic ratios obtained by mixing gRNA from cell lines homozygous for rs2244931 (C/C and G/G) as well as heterozygous (C/G). The normalized non-risk to risk allele ratio of the H3K27ac signal was determined as the ratio $(N/R)_{\text{ChIP}}/(N/R)_{\text{Input}}$ of non-risk/risk allele ratios in ChIP and input DNA samples. In Figure 5B, the

percentage of the non-risk allele RT-qPCR signal in input DNA is ~57.5% and that of the risk allele is ~42.5%. Similarly, the non-risk allele RT-qPCR signal in ChIP DNA constitutes ~92% and the risk allele signal constitutes ~8%. Thus, the normalized (true) non-risk to risk ratio of the H3K27ac signal is $(92/8)/(57.5/42.5) = 8.5$. The one-sided Student's t-test was used to compare percentages of non-risk alleles RT-qPCR signals in input and ChIP DNA (Figure 5B).

CRISPR epigenome editing

The plasmid pLV-dCas9-p300-P2A-PuroR was a gift from Charles Gersbach (Addgene plasmid # 83,889) (Klann et al., 2017). The plasmid pLV hU6-sgRNA hUbc-dCas9-KRAB-T2a-GFP was a gift from Charles Gersbach (Addgene plasmid # 71,237) (Thakore et al., 2015). The plasmid pSPgRNA was a gift from Charles Gersbach (Addgene plasmid #47108) (Perez-Pinera et al., 2013). For dCas9-p300 and dCas9-KRAB experiments, lentivirus was produced by transfecting HEK293 cells with pLV-dCas9-p300-P2A-PuroR and pLV hU6-sgRNA hUbc-dCas9-KRAB-T2a-GFP plasmids, respectively, at Cincinnati Children's Hospital Medical Center's Viral Vector Core facility.

For dCas9-p300 experiments, 5 million K562 cells were incubated for 3 days with the concentrated dCas9-p300 lentivirus at the cell to virus ratio of 1:5 in the presence of 8 µg/ml polybrene. After 3 days, virus-infected cells were selected with 2 µg/ml of puromycin. We named the resulting cells K562-dCas9-p300.

For dCas9-KRAB experiments, 10 million NA07000 cells were spinfected (in 12 well plate, 1 million cells/ml of media, centrifuged at 800Xg for 2 h at 30°C) with the concentrated dCas9-KRAB lentivirus at the cell to virus ratio of 1:5 in the presence of 8 µg/ml polybrene. After spinfection, 1 ml of fresh media was added to each well (2 ml total) and cultured for 4 days at 37°C. Cells were then washed 3 times with fresh cultured media and continued to grow for 10 more days. After 2 weeks of infection, GFP + virus-infected cells were sorted and cultured to grow more GFP + virus-infected cells. We named the resulting cells NA07000-dCas9-KRAB.

For the regions P, E2 and E3 in Figure 2, we designed several gRNAs targeting these regions (see Supplementary Table S3 for the list of gRNA oligos and Supplementary Table S4 for Addgene IDs of the plasmids generated in this study). Each gRNA oligo pair was phosphorylated using T4 PNK, annealed and cloned into BbsI-digested pSPgRNA plasmid. For each of the P, E2, and E3 regions, we generated equimolar pools of gRNA plasmids (see Supplementary Tables S3,S4).

For *BLK* repression experiments, NA07000-dCas9-KRAB cells were transfected with E3 gRNA plasmid together with the empty vector (EV + E3) or the empty vector alone (EV) (see Figure 4). The empty vector is simply the intact pSPgRNA plasmid. As indicated in Figure 4, the total amount of plasmids

FIGURE 6

dCas9-p300 targeting reveals synergistic interaction of regulatory elements. **(A)** Schematics of epigenome editing (activator p300) experiment in K562 cell line. **(B)** P-E3 synergy: upregulation of *BLK* expression when both the *BLK* promoter P and the enhancer E3 are targeted by p300 protein is significantly higher than when p300 is targeted to either P (p -value = 0.004) or E3 (p -value = 0.004) alone. **(C)** E2-E3 synergy: upregulation of *BLK* expression when both enhancers E2 and E3 are targeted by p300 protein is significantly higher than when p300 is targeted to either E2 (p -value = 0.0008) or E3 (p -value = 0.0008) alone. In B-C, the *BLK* expression values shown are relative to the *BLK* expression level in K562-dCas9-p300 cells transfected with empty vector (EV) (the left-most bars in **(B)** and **(C)** have values identically equal to 1).

used in each transfection was 12 ug, with 6 ug of EV plasmid included whenever it was necessary in order to have a balanced total DNA amount of 12 ug. The optimal amount, 12 ug, of plasmids used for transfection in NA07000-dCas9-KRAB experiments above was determined from exploratory transfection experiments performed with E3 gRNA plasmid alone at varying DNA amounts and selecting the amount which resulted in the largest down-regulation of *BLK* expression (data not shown).

For synergy experiments, K562-dCas9-p300 cells were transfected with pairs of gRNA pools (P + E3 or E2+E3), a single gRNA pool together with the empty vector (EV + P, EV + E2, or EV + E3) or the empty vector alone (EV) (see Figure 6). The empty vector is simply the intact pSPgRNA plasmid. As indicated in Figure 6, the total amount of plasmids used in each transfection was 1.5 ug, with 750 ng of EV plasmid included whenever it was necessary in order to have a balanced total DNA amount of 1.5 ug. The optimal amount, 1.5 ug, of plasmids used for transfection in K562-dCas9-p300 experiments above was determined from exploratory transfection experiments performed with E3 gRNA plasmid alone at varying DNA amounts and selecting the amount which resulted in the highest upregulation of *BLK* expression (data not shown).

At 24 h, cells were harvested and mRNA was extracted using Dynabeads mRNA DIRECT kit (catalog # 61,006, Invitrogen). cDNA was generated using SuperScript™ IV VILO™ Master Mix kit (catalog # 11,756,050, Invitrogen). The *BLK* and *FAM167A* mRNA levels were measured by RT-qPCR using TaqMan Fast Advanced Master mix (catalog# 4,444,963, ThermoFisher Scientific) and TaqMan probes for *BLK* (Hs01017458_m1), *FAM167A* (Hs00697562_m1) and *GAPDH* (Hs03929097_g1). The one-sided Student's t-test was used to compare expression levels in Figures 4B,C and Figures 6B,C.

Analysis of capture Hi-C data

The capture Hi-C paired-end sequencing reads were mapped to the SNP-masked hg19 human genome using HiC-Pro software as follows (Servant et al., 2015) (Figure 1B). First, we obtained phased genotype VCF files for NA07000 and NA07056 cell lines from the 1000 Genomes Project (version v5a.20,130,502), and generated two SNP-masked hg19 genomes files for these cell lines. The heterozygous (Ref/Alt) and homozygous alternative allele (Alt/Alt) loci in the genomes were masked as “N” in order to mitigate the reference mapping bias. The individual reads in each mapped paired-end read are evaluated for the presence of

FIGURE 7

Enhancer haplotypes modulate *BLK* expression. (A) Promoter-E1-E2-E3 haplotypes conditioned on promoter risk and non-risk haplotypes. Each row represents a haplotype and each column - a SNP. Nucleotides are color-coded as shown in the circle above the haplotype heatmap (B) Risk haplotypes at enhancers lower *BLK* expression. (C–E) “Risk dosage” effect. The *BLK* expression level tends to decrease as the total number of ‘risk’ haplotypes in the regulatory regions (promoter and enhancers E1, E2, E3) increases. In (B–E), N means non-risk haplotype and R means risk haplotype. NNNN/NNNN and RRRR/RRRR denote multilocus genotypes at P-E1-E2-E3; N/N and R/R denote multilocus genotypes at the promoter; NN/NN, NN/NR and so on in (C–E) denote multilocus genotypes at P-E1, P-E2 or P-E3. See Materials and Methods for details on the notation.

heterozygous SNPs and labeled as one of the following using phased genotype data from the 1000 Genomes Project: parent-1 allele (M), parent-2 allele (P), or allele unassigned (UA). The M-M, M-UA, and UA-M paired-end reads were grouped as “parent-1” and P-P, P-UA and UA-P paired-end reads were grouped as “parent-2” to compute chromatin interaction frequencies on two parental chromosomes at 5 kb resolution. To identify differences in chromatin interaction frequencies of homologous chromosomes, we determined haplotype-specific interaction frequency matrices in 5 kb bins for each replicate library. For n replicate libraries from each cell line, we computed n matrices for parent-1 haplotype and n matrices for parent-2 haplotype. Treating the entries of these matrices as sequence count data with the study design {M, M, ..., M, P, P, ..., P} (n consecutive M’s followed by n consecutive P’s), we determined differences between chromatin interaction frequencies on parent-1 and parent-2 chromosomes using multiHiCompare (version 1.10.0) method (Stansfield et al., 2019) with the following parameters: make_hicexp (zero.p = 0.8, A.min = 5), cyclic_loess (span = 0.2), logfc_cutoff = 0.5, logcpm_cutoff = 0.5,

p.method = “fdr” and p.adj_cutoff = 0.05. Differential chromatin interaction data was uploaded as custom tracks to WashU Epigenome Browser (<https://epigenomegateway.wustl.edu/>) and the images were then exported (Figures 2,3A).

Enhancer haplotype analysis

Using Bayesian approaches to describe “credible sets” of disease-causal SNPs following published methods (Wellcome Trust Case Control Consortium et al., 2012), we have identified the smallest set of SNPs accounting for 95% of the posterior probability from 3,892 European-American SLE cases and 3,464 controls (Rasmussen et al., 2011). This credible causal set at *FAM167A-BLK* locus, henceforth denoted as BLK-CS-12, consists of 12 SNPs that are in high linkage disequilibrium (LD) ($r^2 > 0.9$), spans a 13 kb region near *BLK* promoter. Conditional analysis on any of the 12 markers reduces association for the other 11, consistent with a single genetic association. Since the 12 markers are in perfect linkage disequilibrium with each other,

without loss of generality, we have omitted a rare indel variant (rs202125301) from BLK-CS-12 and used the set of 11 SNPs (Supplementary Table S5), which we denote as BLK-CS-11, in our analyses leading to Figure 7.

We have written a collection of Perl and R codes to perform analyses leading to Figure 7. We obtained phased genotype VCF file for the European population (GBR, FIN, CEU, IBS, and TSI; 503 individuals in total) from the 1000 Genomes Project (version v5a.20,130,502), and retained genetic variants with minor allele frequency (MAF) $\geq 5\%$ for downstream analysis. From the resulting VCF file, we have extracted phased genotype data for 11 SNPs from the BLK-CS-11 set, 24 SNPs from the enhancer E1 region (hg19 coordinate chr8:11,387,781–11,392,710), 13 SNPs from enhancer E2 region (chr8:11,393,832–11,397,791) and 8 SNPs from enhancer E3 region (chr8:11,402,260–11,405,263). These SNP numbers correspond to the number of columns (11 + 24 + 13 + 8) in the heatmap plot in Figure 7A. From the phased genotype data for 11 promoter variants from BLK-CS-11, we extracted 1,006 haplotypes (from 503 individuals), of which 725 are “non-risk” (TGTACCGGGTG), 243 are “risk” (CCCCTTAAACA) and 38 are “idiosyncratic.” We omitted the idiosyncratic haplotypes from the downstream analyses. The rows in the heatmap plot in Figure 7A correspond to the haplotypes, with the rows labeled as ‘Risk’ representing 243 promoter “risk” haplotypes and the rows labeled as “Non-risk” representing 725 promoter “non-risk” haplotypes, respectively. Each entire row in the heatmap represents the concatenation of promoter, E1, E2, and E3 local haplotypes from the same chromosome.

Conditioned on the promoter haplotype, we further stratified haplotypes on the basis of the local haplotype sequences at candidate enhancer E1, E2, and E3 regions as described in detail in the Main text. In Figure 7B, NNNN/NNNN denotes a multilocus genotype at P-E1-E2-E3. It denotes all individuals in the dataset D344 [gene expression and genotype data from 344 European individuals (Lappalainen et al., 2013)] who possess the P-E1-E2-E3 haplotype shown in the lower dotted box in the ‘Non-risk’ block in Figure 7A on both parental chromosomes 8. Similarly, RRRR/RRRR denotes two identical haplotypes from the upper dotted box in the “Risk” block in Figure 7A.

N/N (prom) in Figure 7A denotes individuals from the D344 dataset who possess prom-N (i.e. non-risk) promoter haplotype (TGTACCGGGTG) on both chromosomes 8, with the local haplotypes at E1, E2, and E3 unspecified. In other words, an individual from the N/N (prom) group can have any promoter-E1-E2-E3 haplotype shown in the “Non-risk” block in Figure 7A. Similarly, an individual from the R/R (prom) group can have any promoter-E1-E2-E3 haplotype shown in the “Risk” block in Figure 7A.

NN/RR in Figure 7E denotes the multilocus genotype (TGTACCGGGTG)-(GCGAAAAA)/(CCCCTTAAACA)-(AGTGTG

FIGURE 8
Genetic interactions are enriched at gene regulatory elements. A quantile-quantile (Q-Q) plot of $-\log_{10} p$ -values from the log-likelihood ratio test of genetic interaction. Genetic interactions were separated into two groups. In the GRE-GRE group, both SNPs are located in gene regulatory regions. In the non-GRE-GRE group, at least one SNP is located outside of the regulatory regions.

GG) at promoter-E3, with the local haplotypes at E1 and E2 unspecified. Other multilocus genotypes in Figures 7C–E are similarly defined.

The one-sided Student’s t-test was used to compare *BLK* expression level distributions in the two groups of individuals in Figures 7B–E.

Statistical test of genetic interactions enrichment in regulatory regions

From the dataset D344, we retrieved SNPs from the 143 kb region R143k (hg19 coordinate chr8:11, 331, 000–11,474,000) at the *BLK* locus. The log-likelihood ratio test was used to determine statistically significant genetic interactions. For each pair of SNPs from the region R143k, we fitted a linear ($y = b_0 + b_1x_1 + b_2x_2$) and an interaction ($y = b_0 + b_1x_1 + b_2x_2 + b_{12}x_1x_2$) model to *BLK* expression and genotype data, where y denotes expression level and x_1, x_2 denote 0/1/2 coded genotypes of the two SNPs under consideration. The log-likelihood ratio test was used to determine statistically significant genetic interactions i.e. the test of whether the interaction model explains the observed data better than the linear model does.

For each pair of SNPs from the region R143k, we thus have a p -value from the log-likelihood test of genetic interaction. To test the hypothesis that genetic interactions are enriched in gene regulatory regions at the *BLK* locus, we separated SNPs from the R143k region into two groups: SNPs from the

putative regulatory regions of *BLK*, as defined by the H3K27ac epigenetic mark and REST binding region (see [Figure 2](#); [Supplementary Table S7](#)) (denoted as GRR) and SNPs outside of the putative regulatory regions. For each SNP pair (SNP1, SNP2), if both SNPs belong to GRR, then the SNP pair is of the “GRE-GRE” type in the notation of [Figure 8](#). If at least one of the two SNPs is outside of GRR, the SNP pair is of the “Non-GRE-GRE” type. The question of whether the genetic interactions are predominantly between SNPs located in gene regulatory regions thus reduces to the problem of comparison of the distribution of the genetic interaction log-likelihood *p*-values defined above for the group of GRE-GRE SNP pairs and non-GRE-GRE SNP pairs. We used the quantile-quantile plot (Q-Q plot) plot to show that the *p*-values of SNP-SNP interactions in the GRE-GRE group are more significant than those in the non-GRE-GRE group. One-sided Kolmogorov-Smirnov test was used to compare the distribution of the log-likelihood *p*-values to obtain *p*-value = 0.0003 shown in [Figure 8](#).

Discussion

Why are our findings on genetic interactions important for SLE? After all, credible causal SNPs are clearly localized to the *BLK* promoter region. Our hypothesis is that SNPs located in enhancer regions can further contribute to disease risk by modulating the effects of promoter SNPs on *BLK* expression. Indeed, a previous model proposes that genetic variants in weak linkage disequilibrium (LD) with risk variants can influence disease risk via physical interactions in the 3D chromatin context ([Corradin et al., 2016](#)). Our functional experiments and genetic analyses provide explicit evidence supporting the validity of this model.

In this study, we presented evidence that global haplotype-specific 3D chromatin interactions between regulatory regions can have a strong influence on local allelic gene expression, and consequently, on disease risk. Our capture Hi-C data revealed that many long-range chromatin interactions in the 8p23.1 region are haplotype-specific. Focusing specifically on the *FAM167A-BLK* locus, we found that the *BLK* promoter and the enhancer E3 located 52 kb downstream from the promoter haplotype-specifically interact in the 3D chromatin context, with the interaction being weaker on the SLE risk haplotype, consistent with the reduced expression of *BLK* on the risk haplotype ([Figures 2,3](#)). Interestingly, we found that the enhancer E3 interacts with haplotype-specificity with two nearby enhancers E1 and E2, which are members of the same super-enhancer cluster to which E3 belongs ([Hnisz et al., 2013](#)), with the interactions being weaker on the risk haplotype. We hypothesized that these interactions amplify the enhancer activity of E3. To test this hypothesis, we have performed allele-specific enhancer reporter assay and allele-specific H3K27ac ChIP-qPCR experiments ([Figure 5](#)). Our reporter experiments revealed that enhancer activity of non-risk E3 sequence is ~1.5 times higher than the

activity of risk E3 sequence ([Figure 5A](#)). Consistent with our ‘local enhancer activity amplification due to long-range chromatin interactions’ hypothesis, allele-specific ChIP-qPCR experiments demonstrated that H3K27ac signal at E3 enhancer on non-risk haplotype is ~8.5 times higher than on risk haplotype ([Figure 5B](#)), the reasoning being that enhancer activity in reporter assays lacks long-range chromatin context whereas the H3K27ac ChIP-qPCR measures endogenous enhancer activity in this particular chromatin context. Together, these findings support our hypothesis that local allele-specific enhancer activities are influenced by global haplotype structure due to chromatin looping interactions.

Our chromatin interaction data also revealed that *BLK* promoter interacts haplotype-specifically with a distal repressor REST binding site and the *FAM167A* gene promoter, with the interactions being stronger on the SLE risk haplotype ([Figures 2,3](#)), consistent with reduced expression of *BLK* on the risk haplotype, and the hypothesis that *BLK* promoter is “enhancer-like” and may regulate expression of *FAM167A*, respectively. For recent research on transcriptional regulation by “enhancer-like” promoters, see ([Xu et al., 2011](#); [Dao et al., 2017](#); [Dao and Spicuglia, 2018](#)). We tested our hypothesis on the regulation of *FAM167A* expression by the “enhancer-like” *BLK* promoter using dCas9-KRAB chromatin repressor experiments ([Figure 4](#)). These experiments have provided strong evidence in support of our hypothesis.

These results nominate *FAM167A*, in addition to *BLK*, or both as potential risk genes at the *FAM167A-BLK* locus. If the regulatory structure we present herein is responsible for the change in disease risk for SLE, and maybe, other disorders associated with the *FAM167A-BLK* locus, rather than a different regulatory structure in another cell type, then perhaps *FAM167A* is the true gene mediating disease risk for two reasons. First, down-regulating signal transduction from the B cell receptor by reducing *BLK* expression would seem to be counter-intuitive for a disease like SLE where autoantibody generation is central to pathogenesis. Second, DIORA-1 (the gene product of *FAM167A*) has an activity that could well have a profound influence on the inflammatory response. DIORA-1 is a disordered protein ([Mentlein et al., 2018](#)) that is secreted and binds desmoglein-1 (DSG1) to gain cell entry, which then activates NFκB via its non-canonical pathway by liberating NFκB-inhibitor kinase from DSG1. DIORA-1 appears responsible for much BCR-ABL-tyrosine kinase inhibitor resistance in chronic myelogenous leukemia (CML) ([Yang et al., 2022](#)). Certainly, DIORA-1 has functional properties that make the level of activity of this gene product attractive for mediating SLE risk. An understanding of the evolutionary advantage for *BLK* and *FAM167A* to be reciprocally regulated in the way we describe awaits a deeper understanding of the inter-relationships of the pathways impacted by their two gene products. However, the multiple diseases with risk variants at this locus would be consistent with a continuing evolutionary impact.

Haplotype-specific enhancer-enhancer and enhancer-promoter chromatin interactions ([Figure 2](#)), and evidence for the “local enhancer activity amplification due to long-range chromatin

interactions” hypothesis (Figure 5) have led us to seek functional evidence of synergistic interactions of *BLK* transcriptional regulatory elements. Using dCas9-p300 CRISPR epigenome editing experiments, we have activated the silent *BLK* locus in K562 cells and demonstrated enhancer-enhancer and enhancer-promoter synergies in *BLK* activation (Figure 6).

Our genetic analyses have revealed that enhancer haplotypes can modulate *BLK* expression (Figure 7) and suggested a “risk dosage” model whereby disease risk alleles at multiple regulatory elements at *BLK* locus synergistically decrease gene expression, and consequently, increase disease risk.

These studies have been done with LCLs, which are generally, B cell lines that have been infected by Epstein-Barr virus (EBV), which is strong etiologic candidate for causing SLE and Multiple Sclerosis (MS) (Harley and James, 2006; Bjornevik et al., 2022; Laurynenka et al., 2022). The LCL is a stable transformed cell line expressing the Latency III program of EBV. The EBV gene product and transcription co-factor, EBNA2, is concentrated at SLE and MS risk loci, including *BLK* (Harley et al., 2018, p. 2; Yin et al., 2021). Recently, Afrasiabi et al. (2022), have extended these observations by showing that *BLK* and *FAM167A* are bound by EBNA2 and the products of both genes are differentially expressed as eQTLs in greater magnitude in LCLs than in B cells that are not EBV infected, with *BLK* and *FAM167A* being affected in opposing directions. Both *BLK* and *FAM167A* are correlated with EBV DNA copy number per cell, with the association with *FAM167A* being much more convincing. Finally, the level of EBNA2 in their data is inversely proportional to the level of *BLK* expression. These observations add another level of complexity relating the environment to disease risk that begs for an understanding of how these differences may or may not be components of mechanisms that influence disease risk.

Common SNPs with effect sizes well below genome-wide statistical significance account for a large proportion of “missing heritability” of many traits (Yang et al., 2010). However, mechanistic details of how weak-effect genetic variants contribute to heritability and disease risk remain largely unknown because we still have very limited knowledge of how these variants percolate through the entire cellular and gene regulatory networks (Boyle et al., 2017). Investigations such as those in (Corradin et al., 2016; Boyle et al., 2017), and the present study represent important steps toward deciphering the mechanistic details of the genotype-phenotype map in disease etiology.

Data availability statement

The high-throughput sequencing data from this study have been submitted to the NCBI Gene Expression Omnibus (GEO; <https://www.ncbi.nlm.nih.gov/geo>) under accession number GSE211246. The original contributions presented in the study are included in the article/Supplementary Material. Further inquiries can be directed to the corresponding authors.

Author contributions

IC conceived the study. IC, MS-JR, PT, and JH designed the study. MS-JR and PT performed the experiments. IC, PT, MS-JR, and BN analyzed the data. IC and JH drafted the article. All authors contributed to the article and approved the submitted version.

Funding

This work was supported by funding (to IC) from the Lupus Research Alliance, Arthritis National Research Foundation, National Psoriasis Foundation, and Cincinnati Children’s Research Foundation, and by the following grants (to JH): NIH grants R01 AI024717, R01 AI148276, U01 AI130830, UM1 AI144292, U54 GM104938, and P30 AR073750 and a USDVA Merit Award I01 BX001834.

Acknowledgments

We would like to thank Cincinnati Children’s Hospital Medical Center’s DNA Sequencing and Genotyping Core, and Viral Vector Core for the sequencing and lentivirus production services provided for this study. We would also like to thank Isaac Harley for his comments on the manuscript and for bringing recent work on the functional characterization of *FAM167A* gene product DIORA-1 to our attention.

Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Publisher’s note

All claims expressed in this article are solely those of the authors and do not necessarily represent those of their affiliated organizations, or those of the publisher, the editors and the reviewers. Any product that may be evaluated in this article, or claim that may be made by its manufacturer, is not guaranteed or endorsed by the publisher.

Supplementary material

The Supplementary Material for this article can be found online at: <https://www.frontiersin.org/articles/10.3389/fgene.2022.1008582/full#supplementary-material>

Congenital pseudarthrosis of the tibia (CPT) is a rare congenital bone malformation, which has a strong relationship with Neurofibromatosis type 1 (NF1). NF1 is an autosomal dominant disease leading to multisystem disorders. Here, we presented the genotypic and phenotypic characteristics of one unique case of a five-generation Chinese family. The proband was CPT accompanied with NF1 due to *NF1* mutation. The proband developed severe early-onset CPT combined with NF1 after birth. Appearance photos and X-ray images of the left limb of the proband showed significant bone malformation. Slit-lamp examination showed Lisch nodules in both eyes of the proband. Whole-exome sequencing (WES) and Sanger sequencing confirmed the truncation variant of *NF1* (c.871G>T, p. E291*). Sequence conservative and evolutionary conservation analysis indicated that the novel mutation (p.E291*) was highly conserved. The truncated mutation led to the loss of functional domains, including CSRD, GRD, TBD, SEC14-PH, CTD, and NLS. It may explain why the mutation led to a severe clinical feature. Our report expands the genotypic spectrum of NF1 mutations and the phenotypic spectrum of CPT combined with NF1.

neurofibromatosis type 1, congenital pseudarthrosis of the tibia, ferroptosis, bone deformity, genetic mutation

Introduction

Congenital pseudarthrosis of the tibia (CPT) is a rare type of bone deformity with typical characteristics of pseudarthrosis in early life, pathological fractures of the anterolateral part of the tibia that result in bowing, narrowing of the medullary canal, or a cyst (Crawford, 1986; Hefti et al., 2000). The prevalence is approximately one in 140,000–250,000 births (Crawford and Schorry, 1999; Kesireddy et al., 2018). Previous experience and research suggested that there was a strong relationship between CPT and neurofibromatosis type 1 (NF1) (Crawford, 1986), but the prevalence was heterogeneous worldwide (Hefti et al., 2000; Vander Have et al., 2008). A recent review by van Royen et al. (2016) reported that the prevalence of NF1 in patients with CPT was around 84.0%.

NF1 is caused by mutations in the *NF1* tumor suppressor gene on the 17q11.2 chromosome and affects multiple systems including neurocutaneous and skeletal systems characterized by various clinical manifestations including the typical Café-au-lait macules, Lisch nodules, bone deformity, and multiple neurofibromas (Young et al., 2002; Jett and Friedman, 2010). Treatment for CPT is very difficult and challenging, which is often referred to as one of the most puzzling and frustrating conditions in pediatric orthopedics worldwide (Granchi et al., 2012). Patients may need multiple surgeries frequently to consolidate the pseudarthrosis and unfortunately, refractures occur. After the surgery, there is still a risk of not achieving bone union, and the risk of amputation will be never completely avoided. CPT complicated with NF1 makes the treatment even more challenging, which significantly impairs patients' growth and development, mental health, and quality of life, which imposes a heavy burden on children, families, and society. The etiology of CPT has not been completely understood and little is known about why CPT is closely related to NF1. Hereditary factors play an essential role in pathogenesis.

The tumor suppressor gene *NF1* comprises 350 kb of genomic DNA (Viskochil et al., 1990) and contains 60 exons encoding a large neurofibromin protein of 2,818 amino acids (Marchuk et al., 1991). To date, pathogenic mutations in the *NF1* gene have been detected as point mutations, frame deletions or duplications, indels, and complex rearrangements (Human Gene Mutation Database (HGMD), <http://www.hgmd.org/>). Most of these variations result in the truncated protein product. Thus, the NF1 deficiency or the loss of neurofibromin function is related to the increased Ras activity and a high proliferation rate (Trovó-Marqui and Tajara, 2006). The development of Whole-exome sequencing (WES) makes the diagnosis and potential targeting of gene therapy possible. Here, we reported a novel truncated variant (c.871G>T; p. E291*) in a Chinese pedigree and elucidated the possible functional loss through bioinformatic analysis.

Materials and methods

Proband, pedigree, and clinical assessments

This study was conducted according to the principles of the Declaration of World Medical Association (2013). It has been approved by the Local Research Ethics Committee of the Children's Hospital, Zhejiang University School of Medicine (2022-IRB-148). In March 2022, a boy of 14 years and 11 months visited the Department of Orthopedics in the Children's Hospital, Zhejiang University School of Medicine, Hangzhou, China. The main complaints were deformities of the left ankle and the left limb after birth and the inability to walk due to the severe pain in the left limb for 2 weeks. He was considered as the proband in the present study. In addition, he had scoliosis of the spine and multiple café-au-lait macules all over the body except for the face. Comprehensive examinations and tests were conducted, including X-ray examinations of limbs and spine, three-dimensional computed tomography (CT) of the left tibia and fibula, visual examinations and slit-lamp examination, blood routine examination, liver function, renal function, routine urine test, routine stool test, bone metabolism test, Vitamin D test, blood clotting function test, and detections for Human Immunodeficiency Virus (HIV), Syphilis, Hepatitis B, and Hepatitis C. The family history of NF1 and CPT was asked by the orthopedist and information on the five-generation Chinese family was collected. Based on the above information, the diagnosis of the proband was made as CPT combined with NF1. The proband underwent tibial osteotomy and correction and intramedullary nail fixation. At present, a small amount of callus growth can be seen. His mother and grandmother (i.e., his mother's mother) were observed with café-au-lait macules, dermatofibroma, freckles, and severe scoliosis and kyphosis (only seen in the mother) and a diagnosis of NF1 was made according to the establishing criteria. Grandfather (i.e., mother's father), father, and younger brother of the proband were also included in the present study. They had a relatively good health status without any CPT and NF1-related symptoms or signs.

Whole-exome sequencing

Genomic DNA was extracted from peripheral leukocytes using the Blood Genome Qiagen Blood DNA mini kit (Qiagen). The whole-exome DNA library was prepared by using VAHTS Universal DNA Library Prep Kit for Illumina V3 (Vazyme) and KAPA HyperExome Sequence Capture Kit (Roche, United States). The Illumina DNA Standa ds and Primer Premix Kit (kapa) was used for library quantification, followed by sequencing with the dnBSEQ-T7 gene sequencer (PE150). Raw data with low-quality reads were filtered for quality control. The Burrows-Wheeler Aligner (BWA) sequence alignment method was performed by comparing with the human genome reference (hg19). The mutation sites in the target sequence were identified using GATK software. Familial

segregation analysis of identified mutations was carried out whenever applicable. The variants were validated by Sanger sequencing analysis by using TaKaRa LA PCRTM Kit Ver.2.1 (TaKaRa) with ABI 3500XL (Applied Biosystems) platform. The primers were as follows: TGTAACACGACGCCAGTTTGCCCTTGGGTTTTACATAG (forward) and CAGGAAACAGCTATGACCCCATCAAACAAAGAAACCTAAAATGA (reverse).

Mutation bioinformatics analysis

The American College of Medical Genetics and Genomics (ACMG) Standards and Guidelines for the interpretation of sequence variants were followed in this study (Kalia et al., 2017). The homodimer structure of neurofibromin in open conformation was downloaded from the Protein Data Bank (PDB ID: 7R04). The Pymol visualization tool (<http://www.pymol.org/>) was used to generate the monomer of NF1. The sequence alignments were analyzed by examining multiple sequence alignments using the program Consurf server and Unipro UGENE.

Results

Clinical information

Table 1 presents the clinical manifestations of the three affected members. Regarding the proband (V-1), the onset age of the disease was at birth. He had bone deformities including the unequal length of

lower limbs, bending of left tibia, pseudarthrosis, ankle valgus, and scoliosis of the spine. Multiple café-au-lait macules were distributed all over the body except for the face. Freckles were observed in the axilla and groin. The laboratory tests indicated a low concentration of Vitamin D in the blood and abnormal bone metabolism. The image examinations showed bone deformities, loss of bone mass, and Lisch nodules in both eyes. The mother (IV-2) and grandmother (III-4) had café-au-lait macules distributed all over the body, dermatofibroma around the mouth, on the neck, and in the front chest as well freckles in the axilla and groin. The mother of the proband had severe scoliosis and kyphosis. Figures 1–4 shows the selected results of image examinations, appearance photos, and histopathological findings. Figure 1 shows the presence of pseudarthrosis in the left tibia, valgus of the left ankle, and unequal lengths of the lower limbs. Figure 2 are photos taken under the slit-lamp showing more Lisch nodules in the right eye than that in the left eye. Figures 3A–E shows severe scoliosis and kyphosis of the proband's mother as well as the café-au-lait macules and dermatofibroma on the neck and in the front chest. Figure 3F shows the dermatofibroma distributed around the mouth of the proband's grandmother. Figure 4 are histopathological findings that provided supplementary information to make a diagnosis of neurofibroma.

Genetic characterization and bioinformatic analysis

There are 21 members in this five-generation Chinese family and six individuals were recruited for further study, including

FIGURE 1

Appearance photos and X-ray images of the left limb of the proband. (A) Lateral photo of the pseudarthrosis of left tibia. (B) Photo of pseudarthrosis of the left tibia and the left ankle valgus. (C) Photo of the unequal lengths of the left and right limb. (D) X-ray image of the pseudarthrosis of left tibia. (E) X-ray image of the pseudarthrosis of the left tibia and the left ankle valgus. (F) X-ray image of the unequal lengths of the left and right limb.

three affected individuals and three unaffected individuals. As shown in Figure 5A, the pedigree of the CPT combined with the NF1 patient's family was consistent with autosomal dominant inheritance. To validate the diagnosis, the proband and his

brother, parents, and grandparents (i.e., mother's parents) underwent the WES. The mean read depth reached 20x for 98.9% of the target sequences. This was further confirmed by Sanger sequencing (Figure 5B). The genetic test revealed a

FIGURE 2
Ophthalmological examination under the slit lamp. (A–B) Lisch nodules in the left eye. (C–D) Right eye with multiple Lisch nodules.

heterozygous truncation variant (c.871G>T, p. E291*) of the exon eight in the *NF1* gene (#OMIM: 162,200). The novel mutation was evaluated as a pathogenic mutation according to ACMG guidelines (2017) (Table 2).

The novel truncation mutation is segregated from the phenotype within the pedigree. This truncation mutation was located near the C-terminal of NF1 and caused the loss of most of the structure of the protein (Figure 6A). The structure of NF1 was displayed in the cartoon and the mutation site (p.E291*) was represented in the magenta sphere (Figure 6B). The cysteine-serine-rich domain (CSRD), GAP-related domain (GRD) and Sec14-homologous domain, and pleckstrin homology domain (SEC14-PH) were rendered light pink, light blue, and pale green, respectively. Sequence conservative analysis indicated that the highly conserved loci of the novel mutation (p.E291*) may be involved in essential physiological functions (Figure 7).

Discussion

CPT is a rare disease and the epidemiological data are limited. The estimated prevalence is around one in 140,000–250,000 births. Due to the different classification systems worldwide, the prevalence or the incidence of CPT is heterogeneous across different countries. In Denmark, Andersen et al. reported a CPT incidence of 1:190,000 live births (Andersen, 1971). In Norway, the incidence of CPT was 1:

60,000 when only taking into account the ethnic Norwegian patients and 1:53,000 when all patients born with CPT in Norway were included (Horn et al., 2013). A strong relationship between CPT and NF1 was suggested. A wide variation in NF1 prevalence numbers, ranging from 0.0 to 84.0%, was demonstrated by the literature review due to the various diagnosis standards (van Royen et al., 2016). Based on the NIH diagnostic criteria that have been considered the golden standard for diagnosis of NF1, the prevalence numbers of NF1 among CPT patients were reported as 42.9%, 54.7%, and 84.0% (Heikkinen et al., 1999; Hefti et al., 2000; van Royen et al., 2016). Previous studies suggested a genetic origin for the etiology of CPT combined with NF1. In this study, the symptoms of the proband were considered to be related to genetic factors because the onset age was very early, i.e., at birth, and it presented with severe symptoms. The pedigree of the CPT NF1 patient's family indicated the pattern of autosomal dominant inheritance and Sanger sequencing confirmed the mutation of *NF1*.

CPT is one of the most puzzling pediatric orthopaedic diseases and the treatment is very challenging. Most of the patients have bending tibia within one or 2 years after birth, and they can also have fractures at birth. Tibial deformities and multiple fractures will eventually form pseudarthrosis, resulting in life-long disability. Current treatment for CPT includes conservative and surgical treatment. Before the child could walk, the physician installs a plaster bracket or a plaster tube to fix the ankle and leg. After the child could walk, the ankle and

Abbreviations used are as follows: CSRD, cysteine-serine-rich domain; GRD, GAP-related domain; TBD, tubulin-binding domain; SEC14-PH, Sec14-homologous domain and pleckstrin homology domain; CTD, C-terminal domain; NLS, nuclear localization signal.

leg should be protected with lighter cast support, which may slow down the progression of CPT and avoid the formation of pseudarthrosis and the occurrence of fractures. Surgical treatment can be applied when the child gets older including pseudarthrosis tissue resection, intramedullary rod fixation, wrapped autologous iliac bone transplantation, and Ilizarov annular external fixator compression fixation. Surgery is very challenging and complicating with relatively high risks of nonunion bones, which imposes heavy burdens on the quality of life, psychological well-being, and financial situations of the patients and their families. Mladenov et al. (2020) have reported their treatment protocol for pediatric children with NF1 and tibial pseudarthrosis. Fracture union in tibial pseudarthrosis with satisfactory functional results can be achieved in more than 80% of the children (Mladenov et al., 2020).

The WES could provide further insights into information related to the multisystem disorder. Of note, most of the reported NF1-related variants in the HGMD database are micro changes, and the majority of them are missense/nonsense and small deletions (Figure 8). Three previous studies have investigated the influence of the type of constitutional NF1 mutation on the disease phenotypic variability (Castle et al., 2003; de Luca et al., 2004; Sabbagh et al., 2013). Whereas, limited samples in the survey of Castle et al. and De Luca et al. conferred an ambiguous relationship. Sabbagh et al. revealed a fortuitous association in 565 unrelated patients from the NF-France Network. Understandably, patients with large deletions of the NF1 gene region led to a more severe phenotype. Furthermore, the tendency for truncating mutations to be associated with a

greater incidence of Lisch nodules and a larger number of CAL spots as compared with missense mutations. However, these studies failed to find any statistically significant association of NF1 clinical features with mutation type. A more related survey was urgent to clarify the relationship between different genetic and clinical phenotypes.

In the present study, we found a novel truncation mutation (c.871G>T; p. E291*) in a pedigree with a family history of NF1 disorder. The clinical symptoms vary widely among individuals carrying *NF1* gene mutations. The highly conserved protein consists of a cysteine-serine-rich domain (CSRD), a GAP-related domain (GRD), a tubulin-binding domain (TBD), a Sec14-homologous domain, a pleckstrin homology domain (SEC14-PH) and a C-terminal domain (CTD) (Figure 6A). The pathogenic mechanism of CPT is not clear yet and the deletion or inactivation of the NF1 gene is considered as an important cause (Xu et al., 1990; Basu et al., 1992; Cichowski and Jacks, 2001; Viskochil, 2002; Brekelmans et al., 2019). NF1 gene is a tumor suppressor gene with a high mutation rate and extreme mutation heterogeneity. It encodes neurofibroma protein that enhances the GTPase activity of the RAS protein and negatively regulates the Ras/MAPK signaling pathway (Philpott et al., 2017). NF1 gene mutation causes the loss of function of neurofibroma protein, which may enhance the Ras activity, and then result in abnormal proliferation and differentiation of cell lines such as osteoclast progenitor cells and osteoblast progenitor cells (Sharma et al., 2013). The activated MAPK causes osteoblast differentiation, bone formation disorder, and the increased maturation of osteoclast cells, which also explains why fractures of CPT NF1 patients are difficult to heal (Kuorilehto

FIGURE 7

et al., 2006). In other words, the fracture healing normally requires the expression of the NF1 gene that inhibits the activation of the Ras/MAPK pathway. GRD activates the activity of RasGTPase. It is well known that the multiple RAS downstream effectors including the PI3K, ERK, and RalA are highly expressed in NF1 patients. Thus, the dysfunction of GRD leads to neurofibroma tumor genesis and progression. The CSRD also regulates the GRD function *via* its phosphorylation by both kinase A (PKA) and protein kinase C (PKC) (Izawa et al., 1996; Mangoura et al., 2006). The CTD is also regulated by PKA and then regulates the Ras-GAP activity

negatively (Tokuo et al., 2001; Feng et al., 2004). The functional domain SEC14-PH within the C-terminal region might be implicated in protein and lipid trafficking (Mousley et al., 2007).

The novel truncation mutation (c.871G>T; p. E291*) has not been reported by other literature. Besides our finding, an early study by Zhu et al. (2019) has identified 25 novel variants among 44 NF1 CPT patients in China. On exon 8, there were two novel mutations, i.e., c.731-2A > C and c.786_787insTT (p. (Lys263Leufs*19), which were interpreted as pathogenic according to the ACMG criteria (Zhu et al., 2019). Our results

**FIGURE 8**

Pie chart of *NF1* mutation types on the HGMD website. The micro lesions are made up of missense/nonsense, splicing, regulatory, small deletions, small insertions, and small indels. The gross deletions consist of gross deletions, gross insertions/duplications, and complex rearrangements of repeat variations.

and previous findings have confirmed that the *NF1* loss-of-function variant is a major factor leading to *NF1* CPT. In the present study, we did not detect the lesion tissue. Zheng et al. (2022) collected the periosteum tissue from the pseudarthrosis site of six patients with *NF1*-CPT (i.e., probands) and their unaffected parents. They found that five of six *NF1*-CPT patients (83.3%) had *NF1* inactivation in tissues. In addition, we had to admit that WES may not detect all the *NF1* variants. For instance, non-coding variants from the regulating area of *NF1* may be among the undetected genetic regions (Zheng et al., 2022). Therefore, we recommended using comprehensive detection and analysis of other variants using both the lesion tissue and the blood of patients with and without *NF1* CPT.

The Glu²⁹¹ is located within the N-terminal domain of neurofibromin. This truncated variant resulted in the loss of a series of domains including CSRD, GRD, SEC14-PH, and CTD. The functions of these domains might explain the clinical phenotypes in this pedigree to some extent. Although the research on the *NF1* gene has been well studied in recent years, current clinical therapies still mainly rely on symptomatic treatment and surgery, which alleviated clinical symptoms rather than curing the disease. As a monogenic disease, gene therapy is considered a promising therapy. Multiple studies have transduced the *NF1*-GRD gene into different cell lines via various vectors and successfully reversed the cell phenotype (Hiatt et al., 2001; Thomas et al., 2006; Bodempudi et al., 2009; Bai et al., 2019).

Given the fact that CPT is a progressive disorder, early diagnosis and intervention are warranted to improve the prognosis of the disease. Owing to the complexity of clinical phenotypes, an extended genetic characterization of this multiple system disorder will be helpful in clinical diagnosis as well as treatment. Precise genetic counseling and gene diagnosis are recommended for CPT patients. If the proband in our study could get early gene detection and be provided with the plaster or cast support and specific nutrition support at an early age, the progression of bone deformities might be slowed down and his prognosis might be better. Therefore, based on the data in this study, we call for attention from pediatric orthopedists, other health care professionals, and patients' caregivers and highly recommended screening for pathogenetic mutations.

Data availability statement

The datasets for this article are not publicly available due to concerns regarding participant/patient anonymity. Requests to access the datasets should be directed to the corresponding authors.

Ethics statement

Systemic lupus erythematosus (SLE) susceptibility has a strong genetic component. Genome-wide association studies (GWAS) across trans-ancestral populations show both common and distinct genetic variants of susceptibility across European and Asian ancestries, while many other ethnic populations remain underexplored. We conducted the first SLE GWAS on Egyptians—an admixed North African/Middle Eastern population—using

537 patients and 883 controls. To identify novel susceptibility loci and replicate previously known loci, we performed imputation-based association analysis with 6,382,276 SNPs while accounting for individual admixture. We validated the association analysis using adaptive permutation tests ($n = 10^9$). We identified a novel genome-wide significant locus near *IRS1/miR-5702* ($P_{\text{corrected}} = 1.98 \times 10^{-8}$) and eight novel suggestive loci ($P_{\text{corrected}} < 1.0 \times 10^{-5}$). We also replicated ($P_{\text{perm}} < 0.01$) 97 previously known loci with at least one associated nearby SNP, with *ITGAM*, *DEF6-PPARD* and *IRF5* the top three replicated loci. SNPs correlated ($r^2 > 0.8$) with lead SNPs from four suggestive loci (*ARMC9*, *DIAPH3*, *IFLDT1*, and *ENTPD3*) were associated with differential gene expression ($3.5 \times 10^{-95} < p < 1.0 \times 10^{-2}$) across diverse tissues. These loci are involved in cellular proliferation and invasion—pathways prominent in lupus and nephritis. Our study highlights the utility of GWAS in an admixed Egyptian population for delineating new genetic associations and for understanding SLE pathogenesis.

KEYWORDS

GWAS, lupus, admixture, Egypt, imputation

1 Introduction

Systemic lupus erythematosus (SLE) is a chronic, complex, multi-system autoimmune disease with substantial mortality and morbidity. Prevalence, severity, and sub-clinical manifestations vary significantly across ethnically diverse populations—with an outsized burden on individuals with African, Hispanic, and Asian backgrounds compared to Caucasians (Carter et al., 2016; Lewis and Jawad, 2017; Pisetsky et al., 2017). Additionally, SLE shows remarkable gender bias, affecting ~9–10 times as many women as men.

In addition to epigenetic and environmental contributions, SLE has a very strong genetic component. This is evidenced by high heritability (~66%), familial clustering (sibling recurrence risk ratio ~30), twin studies (~10 times higher concordance rate in monozygotic versus dizygotic twins) (Deapen et al., 1992; Block, 2006; Mak and Tay, 2014; Kuo et al., 2015), and by a growing number of susceptibility loci identified by genome-wide association studies (GWAS) and high-density candidate gene studies [e.g., ImmunoChip (Cortes and Brown, 2011)]. Despite the identification of ~180 SLE susceptibility loci (Bentham et al., 2015; Sun et al., 2016; Langefeld et al., 2017; Molineros et al., 2017; Julia et al., 2018; Wang et al., 2018; Tangtanatakul et al., 2020; Ha et al., 2022), these account for only ~30% of genetic heritability (Yin et al., 2020), indicating that many genes and pathways remain incompletely mapped or even undiscovered.

The statistical power and locus resolution of GWAS and candidate-gene studies can be increased in several ways: larger sample size, deeper genotyping of existing samples, improved imputation and statistical fine-mapping, and most importantly, introducing samples with different allele and haplotype usage than existing samples. Critically, most lupus studies—and most genetic studies in general—are built mainly upon individuals

with European (and to a lesser extent Asian) ancestries (Ha et al., 2022). However, many alleles occur at low frequencies in these ethnicities, preventing statistically meaningful measurement of their effects. The use of underrepresented ethnicities with different allelic usage and recombination hotspots is the single most effective way to increase association power (Wojcik et al., 2019). In addition to providing sufficient power to resolve additional ancestry-independent signals, such studies also illuminate ancestry-specific signals (Goulielmos et al., 2018)—wherein a locus is risk only in a specific ethno-genetic background. Such studies are particularly important in autoimmune diseases like lupus, which afflict non-white ethnicities at much higher rates than whites.

Lack of diversity in the available human genomes deposited in public databases limits our understanding of the genetic underpinnings of complex traits, hinders precision medicine, and contributes to health disparities (Popejoy and Fullerton, 2016; Ben-Eghan et al., 2020). Africans and Middle Easterners are among the populations the most underrepresented in genetic association studies, despite comprising over 1.5 billion people and coming from the birthplace of humanity. Moreover, Africa is home to more genetic diversity than the rest of the world combined (Tishkoff et al., 2009) and as such constitutes a woefully underutilized pool for genetic discoveries. Meanwhile, the Middle East and North Africa were both the cradle of civilization and the largest crossroads of migration in the ancient world, bringing together Africa, Europe, and Asia as empires rose and fell. A recent population admixture study (Schuenemann et al., 2017) showed that Ancient Egyptians were more closely related to Middle Easterners and Europeans than to Africans, with African ancestry increasing after the fall of the Roman Empire. In SLE, striking racial/ethnic differences exist in incidence, disease course and clinical manifestations; genetic

FIGURE 1
Overview and study design.

studies will be helpful to delineate these disparities. However, very few genetic association studies on Egyptians have been performed thus far—and most feature only a few SNPs from a handful of candidate genes (Elghzaly et al., 2015). Therefore, a large-scale genome-wide association study is required to understand the SLE genetic landscape in Egyptians—here, we perform the first such study. The major findings of our study are: 1) nine newly uncovered SLE susceptibility loci with one genome-wide significant, 2) replication of several previously known SLE loci, and 3) remarkable similarities in minor allele frequencies at risk loci between Egyptians and Europeans.

2 Materials and methods

2.1 Systemic lupus erythematosus patients and controls

The overview and design of the study is shown in Figure 1. Patients were informed of the nature of the study, and only those who gave their consent were included in the study. SLE was

diagnosed according to the 1997 update of the Revised American College of Rheumatology (ACR) classification criteria for SLE (Hochberg, 1997) or the “Systemic Lupus International Collaborating Clinic” (SLICC) Criteria for Classification of Systemic Lupus Erythematosus (Petri et al., 2012). Our rheumatologists used both diagnostic criteria, because we had patients of long disease history with established diagnosis based on earlier criteria that preceded the SLICC standard. Patients who were identified as SLE positive after the introduction of the SLICC criteria were diagnosed accordingly and the two subsets, being included in each center’s registries, were recruited for the study as definite cases of SLE. Note that we lack ACR/SLICC information and some demographic data for 26 SLE patients who have left physicians’ care and are no longer available for verification. Patients’ recruitment, clinical examinations, diagnostic laboratory investigations, and data collection were all performed in their corresponding medical centers by expert rheumatology teams and in specialized university laboratories. Data was collected in an *ad hoc* unified Excel spreadsheet and reviewed by senior rheumatology experts. Exclusion criteria included the presence of overlap features or the presence of

other autoimmune diseases except for Sjögren's syndrome. The control group was selected from the same geographical location as the corresponding center. All participants provided informed consent, and the study was approved by the Institutional Review Boards from Oklahoma Medical Research Foundation (OMRF), Oklahoma City, United States (IRB approval number 14–16), and Mansoura University Ethics committee/IRB (MFM-IRB code number R/16.04.81). The recruiting hospitals/universities included Cairo University, Mansoura University, Tanta University, Alazhar University—females only, Beni-Suef University, Benha University, Menofia University, Alexandria University, Ain Shams University, South Valley University, and Assuit University.

Initially, 537 Egyptian SLE patients and 434 controls were recruited for the GWAS study, and DNA samples were extracted from 5 ml whole blood samples collected in EDTA-containing tubes and stored at -20°C . DNA extraction for all samples was done in Germany, according to manufacturer's instructions using the Qiaamp DNA Blood Mini Kit (QIAGEN, Hilden, Germany). To increase statistical power, 449 additional unaffected Egyptian controls [already genotyped in Germany for another GWAS study (Bejaoui et al., 2019)] were added to the study. These controls were recruited from the blood banks of Cairo and Mansoura Universities and approved by the IRBs of both Universities (as mentioned above).

2.2 Demographics

Gender and age distributions for SLE cases and controls (after quality control, described below) are shown in [Supplementary Table S1](#). Overall, females constituted 90% and 64% of cases and controls, respectively. Average ages of cases and controls are comparable. The distribution of major ACR criteria within SLE patients are shown in [Supplementary Table S1](#). Almost all (99%) SLE patients were positive for anti-nuclear antibodies (ANA).

2.3 Genotyping and quality control

Initial samples (537 SLE patients and 434 controls) were genotyped on the Illumina Multi-Ethnic Genotyping Array (MEGA) at the genotyping core facility of OMRF, Oklahoma City, United States. The 449 additional out-of-study controls were already genotyped on the Illumina Infinium Global Screening Array. The out-of-study controls have no genotyping data on the X-chromosome; thus we decided to focus only on autosomal loci. We hope to obtain this missing genotyping data for use in future studies on X-linked traits. We performed strict quality control (QC) on genotyped SNPs in each dataset separately (cases and two sets of controls) as follows: (a) we excluded SNPs with bad clusters due to poor genotyping calls,

(b) we removed SNPs with missing genotype rate ≥ 0.05 , and (c) we filtered out SNPs out of Hardy-Weinberg equilibrium ($p < 0.0001$) and/or minor allele frequency (MAF) $< 0.5\%$. After QC, 295,981 autosomal (chromosomes 1–22) SNPs that overlapped both genotyping arrays remained for further analysis. Of the 537 cases and 883 controls, the GCTA algorithm (Yang et al., 2011) selected 500 cases and 815 controls as being unrelated from one another; the others were excluded. As a final QC step, 42 cases and 46 controls were removed from the cohort due to being outliers from principal components analysis—leaving 458 cases and 769 controls for this study. The inflation factor λ was calculated from the case-control association test on the final, clean cohort (458 cases and 769 controls).

2.4 Statistical power for detecting association

To estimate the ability of our GWAS cohort to support statistically significant associations, we performed a statistical power calculation. The Genetic Association Study Power Calculator server (Johnson and Abecasis, 2017), derived from the CaTS power calculator for two-stage association studies (Skol et al., 2006), was used. We used our final cohort (458 cases, 769 controls) to assess statistical power, while setting the parameter prevalence for SLE to 0.3% (Wang Y. F. et al., 2021).

2.5 Imputation for GWAS samples

We used the Michigan Imputation Server (Das et al., 2016) for imputation on the 22 autosomes. 1,000 Genomes Project data (Phase 3 Integrated Release Version 5 Haplotypes) was used as the reference panel. After imputation, we performed strict QC on post-imputed SNPs as described above (Hardy-Weinberg equilibrium $p > 0.0001$ in controls and/or $\text{MAF} \geq 0.5\%$). About 6.36 million post-imputed SNPs with high imputation quality ($\text{Rs}^2 > 0.7$ for $\text{MAF} \geq 3\%$) were used for downstream analysis.

2.6 Admixture-corrected association analysis with imputed data

To quantify individual ancestry proportion in our Egyptian cohort, we complemented our dataset with published samples from the ancient Near East (Lazaridis et al., 2016) (the historical Fertile Crescent and Levant regions, corresponding to modern-day Egypt, Turkey, Iran, and surrounding nations.) The Near East samples include 294 ancient and 2,068 modern individuals spanning a range of nationalities and ethnicities. In both the Egyptian dataset and Near East public dataset, we excluded SNPs with A/T or C/G alleles and identified ~33,000 common

unrelated SNPs ($MAF > 5\%$ and linkage disequilibrium, $LD\ r^2 < 0.2$) for analysis. Principal components analysis was performed with GCTA (Yang et al., 2011), and genetic ancestry composition was estimated with ADMIXTURE (Alexander et al., 2009).

We performed imputation-based association analyses using mach2dat (Li et al., 2009) before and after admixture correction. (A/T and C/G alleles were recovered during imputation.) ADMIXTURE uses a maximum-likelihood approach to determine admixture proportions of individuals by assuming there are K hypothetical underlying populations among them. We selected $K = 5$ as the best model for the number of ancestral populations and took the first four ancestry proportions as covariates for admixture correction. The inflation factor (λ) was estimated using all admixture-corrected association results from QC-passed SNPs.

We performed multiple-testing correction using permutation (Gao, 2011)—considered the gold standard in GWAS studies. Note that we specifically avoided Bonferroni correction as this assumes independence, which is failed when any SNPs are in linkage disequilibrium—thus producing unacceptably conservative associations (Johnson et al., 2010). Besides, Bonferroni correction suffers several shortcomings, most notably low statistical power for rejecting the null hypothesis (Cohen, 1990, 1994; Perneger, 1998; Nakagawa, 2004) and also performing large amounts of unnecessary testing (Fadista et al., 2016). Critically, permutation analysis controls for low sample-size effects, as all permutations have identical n as the proposal—comparisons are between permutations with identical statistical power *a priori* to produce an association. Thus, we do not fear spurious associations despite our relatively small sample sizes.

2.7 Replication of previously known variants and loci

To replicate previously reported SLE susceptibility loci, we followed a recent study (Ha et al., 2022) that collated 179 statistically-independent non-human leukocyte antigen (HLA) loci as underlying SLE susceptibility. At each risk locus, we defined a boundary as ± 150 kb around the nominated SNP and collated the full set of SNPs in these intervals. Then, we compared this (enlarged) SNP set with the admixture-corrected association results. Using an ancestry-corrected permutation-based analysis, we set the threshold for replication at $P_{\text{perm}} < 0.01$ —stricter than the more commonly used 0.05 threshold, to better exclude false positive associations.

2.8 SNP functional annotation

Functional interpretation of the associated SNP under any GWAS peak is of critical importance in follow-up analysis. Like

most other GWAS studies, many of our identified SNPs concentrate in non-coding DNA, e.g., transcriptional regulatory regions (promoters, enhancers) and non-coding RNA. Therefore, analyzing tissue-specific effects of expression quantitative trait loci (eQTLs) is a promising approach. We used Qtlizer (Munz et al., 2020) for the top SNPs in the novel loci to obtain their eQTLs from several public databases, including GTEx v7 (Consortium, 2013), GEUVADIS (Lappalainen et al., 2013), GRASP (Leslie et al., 2014), Haploreg (Ward and Kellis, 2012), SCAN (Gamazon et al., 2009), seeQTL (Xia et al., 2011), Blood eQTL Browser (Westra et al., 2013), pGWAS (Suhre et al., 2017), ExSNP (Yu et al., 2016), and BRAINEAC (Ramamany et al., 2014). Qtlizer allowed exploration of QTL data for a given list of variants (indels and SNPs) in a fast and efficient manner by integrating many QTL datasets.

2.9 Annotation of long non-coding RNA targets and microRNAs

Target sites of lncRNAs were predicted using the LncRRISearch server (<http://rtools.cbrc.jp/LncRRISearch>) (Fukunaga et al., 2019), built upon RIBlast (Fukunaga and Hamada, 2017), which computationally identifies lncRNA-mRNA interactions through a seed-and-extension approach. For miRNAs, we identified similar sequences in the human genome (GRCh37/hg19) with BLAT on the UCSC Genome Browser (GRCh37/hg19).

3 Results

3.1 Study population and statistical power

After rigorous QC, 458 cases and 769 controls were identified by GCTA (Yang et al., 2011) as unrelated samples and were used for association (Figure 1, Section 2). Due to the small sample size, our study had moderate power (68%) for detection of significant ($p < 1 \times 10^{-5}$) variants with odds ratio (OR) < 1.5 (Supplementary Figure S1). However, for common (minor allele frequency, $MAF \geq 10\%$) SNPs with large effect ($OR \geq 1.6$), our study had high (up to 90%) power. The inflation factor (λ) between cases and controls was 1.06; the QQ plot is shown in Supplementary Figure S2.

3.2 Genome-wide association of SLE

To discover novel SLE susceptibility loci and to replicate previously known SLE risk loci in our Egyptian cohort, we performed a genome-wide imputation-based association study with 6,382,276 SNPs while adjusting for individual admixture (see Section 2). The Manhattan plot showing $-\log_{10} p$ values for SNP associations for our GWAS is shown in Figure 2.

3.2.1 Discovery of novel SLE loci

We identified 28 SNPs in nine novel loci with $P_{\text{corrected}} < 1 \times 10^{-5}$ (Table 1; Supplementary Table S2; Figure 3). The most significant signal, which passed genome-wide significance (rs5839171, $P_{\text{corrected}} = 1.98 \times 10^{-8}$, $P_{\text{perm}} = 3.30 \times 10^{-8}$), is downstream of the Insulin receptor substrate 1 gene (*IRS1*) and miR-5702, a microRNA involved in cellular proliferation and cancer risk (Li K. et al., 2019). *IRS1* is a signaling adapter protein linking activity of insulin and insulin-like growth factor receptors to intracellular signaling cascades, most notably the PI3K/Akt and Erk MAP kinase pathways (Leslie et al., 2014). *IRS1* has been flagged as a risk locus for insulin resistance (Rung et al., 2009) and type II diabetes (Rung et al., 2009; Voight et al., 2010), and also several cancers (Slattery et al., 2004). The best characterized target of miR-5702 is Zinc finger E-box-binding homeobox 1 (*ZEB1*) (Zhang et al., 2018), a transcription factor critically involved in T-lymphocyte differentiation and interleukin-2 signaling (Guan et al., 2018). At this locus, another nearby (1.7 kb) SNP, rs10804331 ($P_{\text{corrected}} = 8.5 \times 10^{-8}$), is a significant eQTL for *IRS1* in CD4⁺ naïve T-cells ($p = 0.002$) and CD16⁺ neutrophils ($p = 0.01$) (Supplementary Table S3). This SNP is also a significant mQTL for methylated CpG cg07514207 in the *IRS1* promoter (Chen et al., 2016), potentially modulating transcription.

The second signal (rs2265634; $P_{\text{corrected}} = 1.14 \times 10^{-6}$) is between Diaphanous homolog 1 (*DIAPH3*), which modulates mTOR signaling and cellular proliferation (Wan et al., 2021), and

Tudor domain-containing protein 3 (*TDRD3*), a chromatin modulator also involved in proliferation (Moret et al., 2017); it is also close to long non-coding RNA *LINC00434*. *LINC00434* appears to target several genes involved in cancer and autoimmunity (Supplementary Table S4). This SNP is a significant ($p = 4.78 \times 10^{-8}$) expression quantitative trait locus (eQTL) for *DIAPH3*, which was a nominally significant ($p = 7.23 \times 10^{-3}$) SLE risk locus in a previous GWAS study (Lee et al., 2014).

The third signal (rs6761645; $P_{\text{corrected}} = 3.35 \times 10^{-6}$) is upstream of Armadillo repeat containing 9 [*ARMC9*, encoding KU-MEL-1 (Kiniwa et al., 2001)], a ciliary basal body protein, mutations of which underlie the systemic inflammatory disorder Vogt-Koyanagi-Harada disease (VKH) (Ohno et al., 2019) and the neurodevelopmental disorder Joubert syndrome (Van De Weghe et al., 2017). KU-MEL-1, over-expressed in melanocytes, appears to be a primary autoantigen in VKH (Otani et al., 2006) and is also associated with vitiligo and autoimmune uveitis. These top three hits were all located in active chromatin, with rs6761645, in particular, overlapping promoter signals in 17 tissues and enhancers in 12 tissues (Ward and Kellis, 2012); having 14 significant eQTL hits (Supplementary Table S3); and being associated with transcription factor binding sites for Hypoxia-inducible factor 1 (HIF1), a critical regulator of inflammation and the DNA damage response (Dehne and Brüne, 2009; Ramachandran et al., 2021). rs6761645 is an eQTL for *PSMD1* (26S proteasome non-ATPase regulatory subunit 1)

(Supplementary Table S3), another proliferation marker (Okumura et al., 2017).

The five other novel signals localized to *ENTPD3/ENTPD3-AS1* (a tumor suppressor (Li M. et al., 2019) that strongly signals through HIF1 (Wang J. et al., 2021) and its associated antisense RNA), *NCK2* [a critical immune adaptor protein linking B-cell receptor activation to PI3K signaling (Cannons et al., 2013)], *IFLTD1* [a ciliary organization protein and cancer risk gene (Wang et al., 2005), also known as *LMNTD1* and *PASIC1*], *AGXT2* [a risk locus of premature myocardial infarct (Yuanfeng et al., 2016)], *DOCK10* [critical in B-cell activation and proliferation (Yelo et al., 2008)], and the microRNA *MIR548AG1*.

Given the prominent role played by microRNAs in cancer (Calin and Croce, 2006) and autoimmunity (Xiao and Rajewsky, 2009), and the fact that miR-548ag1 had the largest effect size of our novel loci [odds ratio = 2.45 (95% confidence interval 1.67–3.59)], we closely examined the apparent involvement of this miRNA in SLE. The miR-548 family was first discovered in colorectal expression arrays (Cummins et al., 2006) and was expanded through bioinformatic searches for miRNAs overlapping repetitive elements (Piriyapongsa and Jordan, 2007). Both the microRNA family itself and putative target sites derive from the *MaeI* repetitive element; these sequences form very stable hairpin structures of ~37 bp in length. miR-548ag1 was discovered from a B-cell tumor line (Jima et al., 2010), suggesting immune involvement. Many other family members are implicated in cancer (Shi et al., 2015; Ke et al., 2016) and autoimmunity (Yu et al., 2017; Cakmak Genc et al., 2018; Li et al., 2018). To further elucidate the biological roles of miR-548ag1, we searched the human genome for miR-548ag1-like sequences (see Section 2), restricting ourselves to loci exhibiting primate-specific insertions [consistent with other verified miR-548 family members (Piriyapongsa and Jordan, 2007)]. We found closely related sequences in UTRs and introns of ten genes—usually overlapping enhancers and/or transcription factor binding sites (Supplementary Table S5). Strikingly, all ten genes have clear immune involvement (Supplementary Table S5). Five of the ten hits are expressed sequence tags (ESTs) of ~90 bp–100 bp and almost certainly represent previously unannotated members of the miR-548 family. Of the remaining five, it is not immediately clear which are microRNAs themselves and which are potential miRNA target sites. Together, these results emphasize the immune system relevance of our SLE risk locus miR-548ag1 and related miR-548 family members.

3.2.2 Replication of known SLE loci

We compared our association results with 179 SLE known loci (see Section 2) and found 97 known loci replicated with at least one significantly ($P_{\text{perm}} < 0.01$) associated SNP. Whenever available, we showed LD with the top published variant to

identify independent associations at known loci (Table 2). The most significant SNPs at each locus are listed in Table 2. Among them, prominent ($P_{\text{perm}} < 5.0 \times 10^{-5}$) signals include *ITGAM-ITGAX* (rs71391210; $P_{\text{perm}} = 2.0 \times 10^{-7}$), *IRF5* (rs80086012; $P_{\text{perm}} = 3.5 \times 10^{-6}$), *DEF6-PPARD* (rs2395623; $P_{\text{perm}} = 4.70 \times 10^{-6}$), *XKR6* (rs2409660; $P_{\text{perm}} = 4.55 \times 10^{-5}$), *IRF1* (rs10586626; $P_{\text{perm}} = 5.43 \times 10^{-5}$), and *TYK2* (rs77389625; $P_{\text{perm}} = 1.91 \times 10^{-4}$). All replicated ($P_{\text{perm}} < 0.01$) SNPs and their nearest genes are shown in Table 2.

3.2.3 Minor allele frequency of associated SNPs and ethnicity

Allelic abundance—most often reported as minor allele frequency (MAF)—is an important measure both to estimate the effect of given SNPs on specific populations and more broadly to compare ancestry and population stratification between diverse populations. Using the 97 total replicated lead SNPs, we compared MAFs in our Egyptian cohort with those of Africans, Europeans, and Asians. We found a remarkable similarity between the MAFs of Egyptians and Europeans

($R^2 = 93\%$)—i.e., the MAF variance in Egyptians was well explained by the MAF variance in Europeans. Conversely, correlation with Africans ($R^2 = 51\%$) and Asians ($R^2 = 59\%$) was markedly lower (Figure 4). Although surprising *prima facie*, these results were supported by our admixture analysis (Supplementary Figure S3).

3.2.4 Functional SNPs from some notable loci

Having identified several new SLE-associated loci, most of which have known roles in both immune homeostasis and other autoimmune disorders, we sought to better establish possible mechanisms for both the loci and the associated SNPs. For our nine novel loci, we first looked for significant ($P < 1 \times 10^{-5}$) eQTLs for both the top SNPs and the larger set of SNPs in linkage disequilibrium ($r^2 > 0.8$) with them. We found several significant ($3.5 \times 10^{-95} < P < 1 \times 10^{-2}$) eQTLs from our new loci, particularly from *ARMC9* (43 SNPs; 25 tissues), *IFLTD1* (5 SNPs; 4 tissues), *DIAPH3* (6 SNPs; 1 tissue), and *ENTPD3* (1 SNP; 10 tissues) (Figure 5A). *IFLTD1* is enriched in the brain, sex organs, and digestive

mono = Monomorphic SNP

tract (<https://www.proteinatlas.org>), and most eQTL signals came from these tissues. *ARMC9* is very strongly expressed in natural killer (NK) cells (<https://www.proteinatlas.org>) and melanocytes (Otani et al., 2006); interestingly, the strongest eQTL signals arose from vascular endothelium and thyroid. Known loci also contained many eQTL SNPs; for example, *IRF1* (58 SNPs; 23 tissues) showed particularly strong eQTL signals. *IRF1* is quite immune cell-specific, and accordingly, the strongest eQTL signals came from blood (Figure 5B).

4 Discussion

Our study represents the first lupus GWAS in North Africans, an underrepresented population in human genetic studies. Previous studies indicated that Egyptians are highly admixed, with substantial ancestry arising from the Middle East, Europe, and Africa—with the extent of European and Caucasus hunter-gatherer (Lazaridis et al., 2016) contribution being higher, and the African contribution being lower, than might be expected from geography. Greater European/Middle Eastern than African ancestry is also supported by whole-genome sequencing (ElHefnawi et al., 2021). Importantly, modern Egyptians are quite divergent from ancient populations. The inclusion of more diverse participants in genomics studies has been shown to significantly increase fine-mapping resolution (Zaitlen et al., 2010; Asimit et al., 2016). Further studies in Egyptians (and other North African and Middle Eastern populations) could potentially reveal more genetic associations, with implications for understanding, diagnosing, and treating disease for Egyptians and all humans.

In this study, we identified nine novel loci; one is genome-wide significant for lupus susceptibility and eight are suggestive. Among 179 known non-HLA SLE susceptibility loci, 97 were successfully replicated—indicating that most lupus susceptibility in Egyptians is ancestry-independent. We also found several loci not previously reported in any populations. Intriguingly, the novel loci were substantially enriched in proteins involved in cellular proliferation and cancer risk. Specifically, Insulin receptor substrate 1 (*IRS1*), the microRNA miR-5702, Diaphanous homolog 1 (*DIAPH3*), Armadillo repeat containing 9 (*ARMC9*, a.k.a. KU-MEL-1), Intermediate filament tail domain containing 1 (*IFLTD1*, a.k.a. *LMNTD1*), immune adaptor protein NCK2 (Labelle-Côté et al., 2011), and Ectonucleoside triphosphate diphosphohydrolase 3 (*ENTPD3*) (Wang J. et al., 2021) all have well-documented roles in cellular proliferation and tumor invasion. Proliferation factors play a prominent role in lupus, particularly in invasion of specific organs in sub-clinical phenotypes, most notably lupus nephritis (Balomenos et al., 2000; Treantrakanpon et al., 2012).

The novel and replicated loci in this study share other features in addition to association with cellular proliferation—for instance, regulation of and by microRNAs, another hallmark of SLE (Dai et al., 2007; Carlsen et al., 2013). Notably, both *IRS1* and *ARMC9* (along with *LRIG2*, *PSPH*, and *SKP2*) are direct targets down-regulated by miRNA-150 (Zhang et al., 2021). miRNA-150 is a critical immune regulator, for instance driving expression of the inflammatory receptor TREM-1 (Triggering receptor expressed on myeloid cells 1) in dendritic cells and contributing to lupus-like symptoms in mice (Gao et al., 2017). More recently, miRNA-150 (along with miRNA-148b) has been proposed as a specific biomarker for lupus nephritis (Alkhateeb and Altamemi, 2021). Two of our novel risk loci even interact at the protein level: NCK2 directly binds to *IRS1* to

FIGURE 4

Comparison of MAFs for the associated SNPs from our Egyptian controls and 1,000 Genomes data.

create an intracellular signal transduction mechanism for signaling through insulin and insulin-like growth factor receptors (Tu et al., 1998; Tu et al., 2001). We performed a sequence search with our novel risk miRNA *miR548AG1* and discovered ten closely related sequences, all of them in introns or UTRs of immune-critical genes (Supplementary Table S5)—many overlapping enhancers and/or transcription factor binding sites. Furthermore, five of these ten hits are ESTs of ~90 bp–100 bp and almost certainly constitute previously unannotated members of the miR-548 family. The clear immune association of all ten closely related sequences further confirms the relevance of our SLE risk locus *miR548AG1*.

Our study very carefully controlled for admixture in estimating effect size and significance level. This was a critical step, as multiple loci became more significant or less significant once controlled for admixture (Tables 1, 2; Supplementary Table S1). The most substantive change was at the novel locus *IRS1/miR-5702*, where the top SNP rs5839171 achieved genome-wide significance after admixture correction ($P_{\text{uncorrected}} = 1.70 \times 10^{-7}$, $P_{\text{corrected}} = 1.98 \times 10^{-8}$). This remains significant ($P_{\text{permuted}} = 3.3 \times 10^{-8}$) after 10^9 permutations. This emphasizes the utility of admixed populations, like Egyptians, in studying novel gene discovery.

To assess the replication of previously known loci [Table 1 from (Ha et al., 2022)], we implemented a very large (10^7 – 10^9 combinations) ancestry-adjusted permutation analysis on our data. Critically, permutation analysis controls for low sample-size effects, as all permutations have identical n as the proposal—comparisons are between permutations with identical statistical power *a priori* to produce an association. Using the ancestry-corrected permutation-based analysis, we set threshold for replication at $p < 0.01$. Here we further explain our reasoning behind the robustness of our permutation analysis and some of its findings.

First, a recent large-scale ($n > 208,000$) SLE GWAS meta-analysis on East-Asian populations identified rs956237 (GWAS lead variant; intron of *LEF1*, Lymphoid enhancer-binding factor 1—a leukocyte transcription factor) at 4q25 as a novel susceptibility locus (Yin et al., 2020; $p < 4.0 \times 10^{-11}$). Reassuringly, a companion transcriptome-wide association study (TWAS) using data from Asian samples also strongly indicated *LEF1* as the primary gene underlying 4q25 association (Yin et al., 2020; $p < 1.3 \times 10^{-10}$). However, our primary reference (Table 1 from Ha et al., 2022) nominated rs58107865 instead of rs956237 as lead SNP. In our study, we

found that rs58107865 does not exist in the African/Egyptian population. Instead, we discovered an association with another intronic *LEF1* SNP (rs10516550, $p = 0.008$), common in African/European/Hispanic populations (but not Asian). Of course, this SNP needs to be independently replicated in a population with similar ethnic background. But we believe that it's appropriate to cautiously interpret this in the replication category.

Second, *NCF2* is a very well-known SLE locus, where multiple studies (Cunninghame Graham et al., 2011; Yin et al., 2020) including ours (Kim-Howard et al., 2014) have reported non-coding and at least 3 independent ethnicity-specific coding variants within *NCF2* passing genome-wide significance in Asian/Hispanic (rs13306575), European/African-American (rs17849502) and African-American (rs35937854) populations. This locus was represented by rs13306575 in our reference data (Table 1 from Ha et al., 2022). In our data, we found evidence of association (ancestry-adjusted permutation $p = 0.004$) with nearby (< 150 bp) rs17849502. Thus, we have found essentially the same result as the prior studies; however, this real association falls below the strict threshold set by the Bonferroni correction ($p = 0.05/179 = 0.00027$). Our non-parametric permutation analysis, however, detects this locus as a significant association, which we believe is supported by the preponderance of evidence.

Although the sample sizes in the current study are not overly large, we had the power to attain multiple noteworthy discoveries for several reasons: 1) The highly admixed Egyptian population gave us the power to discover nine novel loci, one of which achieved genome-wide significance. 2) Our data attained a remarkable replication rate (97 out of 179 loci; 54%)—increasing confidence in both known and novel loci, and supporting the notion that despite different genetic backgrounds, underlying loci and risk alleles are broadly conserved across ethnicities (Marigorta and Navarro, 2013). Over 80% of our replicated loci arose from GWASs on Europeans, indicating broad concordance of genetic risk. However, it is important to note that the studies included in Ha et al. (2022) were performed on populations with large sample sizes and statistical power. Egyptians have a stronger contribution from Middle Eastern ancestries than European (Wohlers et al., 2020), and their population history and admixture proportions are different. Moreover, our sample size was relatively small. Future studies will boost sample sizes and further address the other aspects. 3) We found several common pathways shared by the known and new loci, increasing the robustness of the observations, and laying out the foundation for further experimental studies to establish a clear mechanistic basis for these loci contributing to SLE risk and progression.

However, we also acknowledge that lack of an independent replication, especially for the novel associations, is a limitation of

this study. Therefore, in addition to strengthening the observations and establishing mechanisms, further studies with larger sample sizes will clearly delineate the ancestry-independent and ancestry-specific components of SLE association.

Institutional Review Board Statement: The study was conducted in accordance with the Declaration of Helsinki and approved by the Institutional Review Board of the Oklahoma Medical Research Foundation (IRB approval number 14–16), and Mansoura University (Egypt) Ethics committee/IRB: MFM-IRB code number R/16.04.81.

Informed Consent Statement: Informed consent was obtained from all subjects involved in the study.

Data availability statement

The original contributions presented in the study are included in the article/Supplementary Materials, further inquiries can be directed to the corresponding authors.

Ethics statement

The studies involving human participants were reviewed and approved by Institutional Review Board of the Oklahoma Medical Research Foundation And Mansoura University Ethics Committee/Institutional Review Board. The patients/participants provided their written informed consent to participate in this study.

Author contributions

Conceptualization, GR and SN; Data curation, AAE, CS, LL and MTH; Formal analysis, CS and SN; Funding acquisition, SI and SN; Investigation, ZT, MA, WA, IE-S, ME, AnA, SH, NS, AH and ENA; Methodology, CS, LL and SN; Resources, NMK, MB, MTH, MAH, MNS, EE, ZT, MA, WA, IE-S, ME, AnA, SH, NS, AS, AmE, AmH, KR, HE-T, AY, FE, AAH, AsA, EmA, DF, SE-B, ME, ENA, and SN; Software, CS, LL, NK, MB and SN; Supervision, NK, SI, GR and SN; Validation, AAE, CS, MAH, MNS and SI; Visualization, AAE, SI, GR and SN; Writing–review and editing, AAE, LL, CS, SE-K, GR and SN. All authors have read and agreed to the published version of the manuscript.

Funding

This research was funded by the University of Lübeck and by the National Institutes of Health, grant numbers MD007909 and AR060366.

Acknowledgments

We thank all patients with SLE and healthy controls who participated in this study. We also thank the research assistants, coordinators, and physicians who helped in the recruitment of subjects for this project.

Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

The causal association between genetically regulated 25OHD and chronic obstructive pulmonary disease: A meta-analysis and Mendelian randomization study

Min Yang¹, Bo Pang^{2,3}, Qiong Wang^{2,3}, Zhixin Zhang^{4*} and Wenquan Niu^{5*}

¹Department of Acupuncture and Moxibustion, Guang'anmen Hospital, China Academy of Chinese Medical Sciences, Beijing, China, ²Graduate School, Beijing University of Chinese Medicine, Beijing, China, ³Department of Pediatrics, China-Japan Friendship Hospital, Beijing, China, ⁴International Medical Services, China-Japan Friendship Hospital, Beijing, China, ⁵Institute of Clinical Medical Sciences, China-Japan Friendship Hospital, Beijing, China

Backgrounds and objectives: Chronic obstructive pulmonary disease (COPD) is a multifactorial disease under genetic control. We present a meta-analysis to examine the associations of vitamin D binding protein (VDBP) gene rs7041 polymorphism with the risk of COPD and changes in circulating 25OHD concentrations.

Methods: A literature search, quality assessment, and data extraction were conducted independently by two investigators. Data are expressed as odds ratio (OR) or weighted mean difference (WMD) with a 95% confidence interval (CI). The inverse variance weighted method (IVW) in R (version 1.1.456) was applied to calculate the Mendelian randomization coefficient.

Results: A total of 13 articles with 3,667 participants were meta-analyzed. The rs7041-GT genotype was associated with a 49% reduced COPD risk (OR: 0.51, 95% CI: 0.30 to 0.88, $p = 0.014$) compared to the rs7041-TT genotype. Carriers of the rs7041-GT genotype had significantly higher concentrations of circulating 25OHD than those with the rs7041-TT genotype (WMD: 0.32 ng/ml, 95% CI: 0.09 to 0.55, $p = 0.006$). Under the assumptions of Mendelian randomization, and assuming a linear logistic relationship between circulating 25OHD and COPD, an inverse association was noted after using VDBP gene rs7041 polymorphism as an instrument (WMD: -2.07 , 95% CI: -3.72 to -0.41 , $p = 0.015$). There was a low probability of publication bias.

Conclusion: We observed significant associations of VDBP gene rs7041 polymorphism with the risk of COPD and changes in circulating 25OHD concentrations. Importantly, we found a causal relationship between genetically regulated 25OHD concentrations and COPD risk.

KEYWORDS

chronic obstructive pulmonary disease, vitamin D binding protein, polymorphism, meta-analysis, Mendelian randomization

Introduction

Chronic obstructive pulmonary disease (COPD) places a major burden on individuals and public health systems (Cho et al., 2022). The Global Burden of Disease study estimated that 3.2 million people died from COPD in 2015 worldwide, representing an increase of 11.6% compared with 1990 (GBD 2015 Chronic Respiratory Disease Collaborators, 2017). In China, the overall prevalence of spirometry-defined COPD was 8.6%, accounting for nearly 100 million patients with COPD (Wang et al., 2018). COPD prevention should be an urgent strategy that can be implemented by determining potential risk factors and identifying persons who are at risk of developing COPD and who could be targeted for preventive measures.

COPD is a multifactorial disease under genetic control (Marsh et al., 2006; Agustí et al., 2022). The heritability of COPD has been estimated to be 37.7% (Zhou et al., 2013), which emphasizes a clear rationale for the determination of COPD-susceptibility genes or genetic alterations (Silverman et al., 2011; Silverman, 2020). Dozens of genome-wide association studies have been undertaken to decipher the genetic linings of COPD (Pillai et al., 2009; Hansel et al., 2015; Wain et al., 2017); however, one of the major challenges in investigating genetic determinants is heterogeneity. Currently, the list of candidate genes for COPD is constantly being improved and updated. One of the most widely evaluated genes is the gene coding for the vitamin D binding protein (*VDBP*).

The human *VDBP* gene is localized in chromosome 4q11-q13; it has three commonly recognized haplotypes (GC-1F, GC-1S, and GC-2) and rs7041 polymorphisms are one of the most common non-synonymous single-nucleotide polymorphisms (SNPs) for the haplotypes (Cleve and Constans, 1988). The three haplotypes have been reported to have a diverging affinity to 25OHD, the marker that is the best indicator of circulating vitamin D concentrations (Arnaud and Constans, 1993). In addition, *VDBP* genetic alterations have been found to be associated with vitamin D deficiency (Chishimba et al., 2010; Wood et al., 2011). The susceptibility of *VDBP* haplotypes to COPD risk has been widely evaluated. A meta-analysis by Khanna et al. (2019) showed that the GC-1F haplotype and the GC-1F/1F genotype in the *VDBP* gene impose a significant genetic risk for COPD among Asians. In another meta-analysis by Xie et al. (2015), it was found that the GC-1F homozygote may be a risk-conferring factor for COPD and that the GC-2 homozygote may be a protective factor against COPD. To the best of our knowledge, no pooled evidence exists currently on rs7041 polymorphism in the *VDBP* gene associated with COPD. At present, this association is the subject of much debate. For example, Li et al. (2014) found that homozygous carriers of the rs7041 T allele had enhanced susceptibility to COPD, whereas Ishii et al. (2014) failed to detect any significant link between rs7041 and COPD. The causes of these inconsistent findings could be explored by a comprehensive synthesis of published association studies.

To seek the possible causes and offer research insights, we present a meta-analysis to examine the associations of *VDBP* gene rs7041 polymorphism with the risk of COPD and changes in circulating 25OHD concentrations. In the case of statistical significance being found for both associations, we attempt to explore the possibly causal implications of circulating 25OHD in the development of COPD by adopting the Mendelian randomization technique and using rs7041 polymorphism as an instrument.

Methods

This meta-analysis was conducted followed the guidelines in the preferred reporting items for systematic reviews and meta-analyses (PRISMA) statement (Moher et al., 2009). The PRISMA checklist is provided in Supplementary Table S1.

Search strategy

A literature search was carried out in the three online databases (PubMed, EMBASE, and Web of Science) up March 10, 2022, including articles ahead of publication. The following keywords were used in searching: (“Vitamin D binding protein” OR “VDBP” OR “VDB” OR “DBP” OR “Gc-globulin” OR “Gc-globulin” OR “GC”) AND (“COPD” OR “chronic obstructive pulmonary disease”) AND (“polymorphism” OR “SNP” OR “variant” OR “variation” OR “mutation” OR “single nucleotide polymorphisms”).

Two authors (MY and BP) completed the literature search independently, and any disagreement was solved by discussion. In addition, the references of major reviews or meta-analyses were also checked for potentially eligible articles that were not identified by the two authors.

Inclusion criteria

Articles eligible for inclusion in this meta-analysis must simultaneously meet the following criteria: 1) case-control design; 2) published in the English language; 3) providing genotype counts of *VDBP* gene rs7041 polymorphism in COPD patients and controls or mean or median values of circulating vitamin D concentrations across rs7041 genotypes; 4) a clear definition of COPD [COPD is diagnosed by doctors or according to the Global Initiative for Chronic Obstructive Lung Disease (GOLD) or American Thoracic Society (ATS) guidelines]; and 5) a validated genotype assaying method. Moreover, in cases when more than one article was published using the same or part of the same sample of study participants, the article using the largest sample size was included.

FIGURE 1

Flow diagram for the selection of qualified articles.

Exclusion criteria

Articles were excluded if any one of the following criteria was met: 1) published in form of a review, correspondence, comment, conference abstract, case report, case series, or clinical trial; 2) a clinical outcome other than COPD; and 3) the lack of a control group.

Data extraction

Data were extracted from each eligible article independently by two authors (MY and BP) according to a predefined template, covering the surname of the first author, year of publication, country where the study was performed, ethnicity, sample size, source of controls, matched condition, diagnosis criteria of COPD, genotype counts of rs7041 polymorphism between

patients and controls, mean or median 25OHD concentrations across rs7041 genotypes in patients or controls or both, and baseline characteristics of study participants including age, gender, body mass index (BMI), percentage of smokers, smoking exposure (cigarette pack-years), smoking status, forced expiratory volume in 1 s (FEV₁), FEV₁ predicted ratio, forced vital capacity (FVC), FVC predicted ratio, and FEV₁/FVC, if available.

Statistical analyses

STATA software version 14.1 (StataCorp, College Station, TX, United States) was utilized in this meta-analysis. The weighted odds ratio (OR) and the 95% confidence interval (CI) were calculated to quantify the association of *VDBP* gene rs7041 polymorphism with the risk of COPD. The weighted

mean difference (WMD) and 95% CI were calculated to quantify the changes of circulating 25OHD concentrations between genotypes of this polymorphism in COPD patients or controls or both ($p < 0.05$; statistically significant). The Hardy-Weinberg equilibrium for *VDBP* gene rs7041 polymorphism was calculated using the R package “GWASExactHW” (version 1.1.456), and $p > 0.05$ indicated no deviation from the Hardy-Weinberg equilibrium.

The fraction of variation owing to heterogeneity was estimated using I^2 -squared (I^2). A larger I^2 value is indicative of a higher probability of between-study heterogeneity. Significance for I^2 was set at 50% (Higgins et al., 2003). Whatever the magnitude of heterogeneity, the random-effects model was used to calculate effect-size estimates. The causes for between-study heterogeneity

were explored from clinical and methodological aspects by subgroup analyses and meta-regression analyses.

Cumulative analyses were performed to evaluate the influence of the first publication on the association between *VDBP* gene rs7041 polymorphism and the risk of COPD on subsequent publications on the same subject over time. In addition, sensitivity analyses were performed to evaluate the contribution of single publications to pooled effect-size estimates by sequentially omitting one publication each time and deriving estimates from the remaining publications.

Publication bias was evaluated using Begg’s funnel plots and Egger’s regression asymmetry tests. The Egger test can detect funnel plot asymmetry by quantifying the probability of publication bias at a significance level of 10%. In addition, the

trim-and-fill method was used to estimate the number of potentially missing publications leading to publication bias and to derive corrected pooled estimates.

The Mendelian randomization technique was employed to estimate the causal influencer of a modifiable risk factor from observational data on clinical outcomes (Smith and Ebrahim, 2003). The inverse variance weighted method (IVW) (Burgess et al., 2013) in the R programming environment (version 1.1.456) was applied to calculate the Mendelian randomization coefficient in this meta-analysis.

Results

Eligible studies

The initial search yielded 79 potentially relevant publications. Application of the inclusion and exclusion criteria revealed

13 eligible articles involving 3,389 participants in the final analysis (Horne et al., 1990; Ishii et al., 2001; Ito et al., 2004; Laufs et al., 2004; Janssens et al., 2010; Shen et al., 2010; Ishii et al., 2014; Jung et al., 2014; Maheswari et al., 2014; Al-Azzawi et al., 2017; Chuaychoo et al., 2018; Jolliffe et al., 2018; Gao et al., 2020). The selection process with specific reasons for exclusion is presented in Figure 1. Finally, data from the 3,667 participants were pooled. Data on circulating 25OHD changes across the rs7041 genotypes were extracted from two articles involving 540 patients and 152 controls (Janssens et al., 2010; Jolliffe et al., 2018).

Study characteristics

The baseline characteristics of the study populations are summarized in Table 1. Of the 13 eligible articles, seven were performed among Asians (Ishii et al., 2001; Ito et al., 2004; Shen

A Heterozygous genotype model (GT vs TT)**B Homozygous genotype model (GG vs TT)****FIGURE 5**

et al., 2010; Ishii et al., 2014; Jung et al., 2014; Maheswari et al., 2014; Chuaychoo et al., 2018), four among Caucasians (Horne et al., 1990; Laufs et al., 2004; Janssens et al., 2010; Gao et al., 2020), one among a Middle Eastern population (Maheswari et al., 2014), and one among a mixed population (Jolliffe et al., 2018). Total sample sizes ranged from 100 to 517. A total of seven articles were conducted with matched patients and controls. There was no deviation from the Hardy–Weinberg equilibrium for *VDBP* gene rs7041 polymorphism. Table 1 also shows the quality assessment of all the qualified articles by using the Newcastle–Ottawa scale (NOS) tool for cohort studies.

Overall analysis: *VDBP* and COPD

As shown in Figure 2, the association of *VDBP* gene rs7041 polymorphism with the risk of COPD was tested under four genetic models: allele model (rs7041-G vs. rs7041-T); homozygous genotype model (rs7041-GG vs. rs7041-TT); heterozygous genotype model (rs7041-GT vs. rs7041-TT); and dominant model (rs7041-GG + GT vs. rs7041-TT). This association was significant under the heterozygous genotype model and the dominant model, with the odds of having COPD being 0.51 (95% CI: 0.30 to 0.88, $p = 0.014$) and 0.68 (95% CI: 0.46 to 0.99, $p = 0.047$), respectively; however, there was moderate evidence of heterogeneity between studies for both models, with a corresponding I^2 value of 77.4% and 77.6%, respectively.

Subgroup analyses: *VDBP* and COPD

Given the significant heterogeneity in the overall analyses, explorations were undertaken by subgroup analyses according to ethnicity, sample size, source of controls, matched condition, and diagnosis criteria of COPD, respectively (Table 2). Under the heterozygous genotype model, the association of *VDBP* gene rs7041 polymorphism with COPD was potentiated in Caucasians (OR: 0.16, 95% CI: 0.03 to 0.97, $p = 0.046$), in studies with matched patients and controls (OR: 0.19, 95% CI: 0.06 to 0.58, $p = 0.004$), in studies with doctor-diagnosed COPD (OR: 0.01, 95% CI: 0.00 to 0.10, $p < 0.001$), and adopting ATS criteria (OR: 0.44, 95% CI: 0.23 to 0.85, $p = 0.014$). Under the dominant model, COPD risk was significantly reduced in large studies (OR: 0.68, 95% CI: 0.48 to 0.95, $p = 0.025$), in studies enrolling population-based controls (OR: 0.58, 95% CI: 0.40 to 0.84, $p = 0.004$), in studies involving Caucasian populations (OR: 0.56, 95% CI: 0.38 to 0.83, $p = 0.004$), in studies with doctor-diagnosed COPD (OR: 0.35, 95% CI: 0.14 to 0.88, $p = 0.025$), and in ATS-criteria-based COPD (OR: 0.59, 95% CI: 0.36 to 0.97, $p = 0.036$). As shown in Table 2, the heterogeneity of each subgroup of race was still significant with a corresponding I^2 value of 78.1% in the Asian group and 81.8% in the Caucasian group, indicating that race was not the cause of heterogeneity under the heterozygous genotype model. Under the allele model and the homozygous genotype model, there was no noticeable significance across all subgroups.

Meta-regression analyses: *VDBP* and COPD

Further explorations on the causes of heterogeneity were performed using meta-regression analyses via modeling age, male composition, BMI, percentage of smokers, smoking exposure (cigarette pack-years), FEV₁, FEV₁ predicted ratio, FVC, FVC predicted ratio, and FEV₁/FVC in cases and controls under the four genetic models. However, there was no detectable significance for all factors ($p > 0.05$).

Cumulative and sensitivity analyses: *VDBP* and COPD

The impact of the first published article on subsequent articles was not significant for the association between rs7041 polymorphism and COPD in cumulative analyses (Supplementary Figure S1). In addition, the impact of any single article on pooled estimates was also not significant in sensitivity analyses (Supplementary Figure S2).

Publication bias: *VDBP* and COPD

The Begg's funnel plots seemed symmetrical for the association of rs7041 polymorphism with COPD risk under the allele, homozygous genotype, heterozygous genotype, and dominant models (Figure 3). This symmetry was confirmed by the Egger tests, with a corresponding probability of 0.725, 0.869, 0.249, and 0.276, respectively, indicating a low likelihood of publication bias.

25OHD changes and rs7041 genotypes

Changes in circulating 25OHD concentrations across rs7041 genotypes were assessed. As shown in Figure 3, circulating 25OHD concentrations were significantly elevated in rs7041-GT genotype carriers (WMD: 0.32 ng/ml, 95% CI: 0.09 to 0.55, $p = 0.006$) and rs7041-GG genotype carriers (WMD: 0.58 ng/ml, 95% CI: 0.30 to 0.80, $p < 0.001$) compared to rs7041-TT genotype carriers, with low evidence of heterogeneity ($I^2 = 22.2$ and 1.4%, respectively), indicating no significant heterogeneity. In other words, race was not a significant cause of heterogeneity in our meta-analysis. The Begg's funnel plots seemed symmetrical for the association of rs7041 polymorphism with the changes of 25OHD concentrations under homozygous genotype and heterozygous genotype models (Figure 4).

Mendelian randomization analyses

Analogous to a randomized controlled trial, Mendelian randomization is developed as a viable strategy to obtain unconfounded and unbiased estimates of causal relevance from observational data. To infer a causal relationship between exposure and disease outcome, two important prerequisites must be met: 1) the selected genes are significantly correlated with intermediate phenotypes or exposure; and 2) the selected genes are significantly correlated with the condition of the disease outcome (Sheehan et al., 2008). To apply R package's "IVW" for Mendelian randomization analyses, we need the data consisting of the OR and 95% CI of rs7041 polymorphism across COPD patients and controls as well as the OR and 95% CI of circulating 25OHD changes across rs7041 polymorphism under the background of case control studies about COPD patients and controls as shown in Figure 2 and Figure 5, which show that the two important prerequisites mentioned above were both met properly. Specifically, the causal estimate was obtained by regression of the associations with the outcome on the associations with the risk factor, with the intercept set to zero and weights being the inverse variances of the associations with the outcome when the "IVW" package was applied (Burgess et al., 2013). With a single genetic variant, this was simply the ratio method (Burgess et al., 2013). Therefore, assuming a linear logistic relationship between circulating 25OHD concentrations and the risk of COPD, an inverse association (WMD: -2.07, 95% CI: -3.72 to -0.41, $p = 0.015$) was noted after using *VDBP* gene rs7041 polymorphism as an instrument for Mendelian randomization analyses.

Discussion

In this meta-analysis, we aimed to evaluate the association of *VDBP* gene rs7041 polymorphism with the risk of COPD and circulating 25OHD changes. After integrating the results of 13 articles and 3,389 participants, we observed significant associations of this polymorphism with the risk of COPD and changes in circulating 25OHD concentrations. Importantly, under the rationale of Mendelian randomization, we found a causal relationship between genetically regulated 25OHD concentrations and COPD risk. To the best of our knowledge, this is the first meta-analysis to date that has interrogated the causality between circulating 25OHD and COPD in the literature.

The association of *VDBP* gene rs7041 polymorphism with COPD risk has been widely studied. Li et al. (2014) found that COPD patients were at high risk of vitamin D deficiency, and that carrying the rs7041-T allele had an impact on serum 25OHD concentrations that were closely related to COPD susceptibility. In contrast, Ishii et al. (2014) reported that distributions of rs7041 genotypes were comparable between COPD patients

and controls. This inconsistency is likely due to inadequate sample size, patient selection, or lack of adjustment for confounders. To address this point, we performed subgroup analyses and found that the association between the rs7041-GT genotype and COPD risk was significant in populations of Caucasian origin and in studies with matched patients and controls. In view of this ethnic difference, we suggest building a candidate list of susceptible genes for COPD in each ethnic group.

Growing evidence shows that vitamin D is a promising biomarker in the development of COPD (Fu et al., 2021). The results of Fu et al. (2021) showed that vitamin D was inversely correlated with inflammatory signaling in patients with COPD, and that vitamin D may be a vital mediator of the progress of COPD in patients with low vitamin D levels. *VDBP* gene rs7041 polymorphism is responsible for the binding and transport of vitamin D analogs, as well as certain immune functions (Rozmus et al., 2020; Abdelaziz et al., 2021; Rozmus et al., 2022). In agreement with the findings of this meta-analysis, many studies have supported the close relationship between *VDBP* genetic alterations and circulating 25OHD concentrations. For instance, Alharazy et al. (2021) showed that the mutation of rs7041 polymorphism was associated with total 25OHD concentrations in postmenopausal women in Saudi Arabia, and the *post hoc* test indicated that total 25OHD concentrations were lower in carriers of the rs7041-TT genotype than carriers of the rs7041-GG genotype. In a separate study, Al-Daghri et al. (2019) reported that median 25OHD concentrations in carriers of the rs7041-GG genotype were significantly higher than in rs7041-TT genotype counterparts. In the present meta-analysis, we found that circulating 25OHD concentrations were significantly higher in carriers of the rs7041-GT genotype than those with rs7041-TT genotype and, importantly, that genetically regulated 25OHD in circulation played a causal role in the pathogenesis of COPD by means of the Mendelian randomization technique. Nevertheless, we concede that our findings are preliminary and that further independent validations are necessary.

Despite the clear strengths of this meta-analysis, including the large sample size and the adoption of the Mendelian randomization technique to infer causality between circulating 25OHD and COPD, several limitations should be acknowledged. First, caution should be taken when interpreting the relationship of circulating 25OHD concentrations with COPD because only two studies, with only 440 COPD patients and 152 controls, were available for analysis. Second, only articles published in the English language were retrieved, which might yield possible selection bias, even though our funnel plots and statistical tests revealed that this bias was unlikely. Third, although several subgroup analyses were conducted to explore potential heterogeneity, including analyses grouped by race, these subgroup analyses could not demonstrate that the target loci are conserved across different ancestries, and we only chose *VDBP* gene rs7041 polymorphism as an instrument for Mendelian

randomization analysis, while other *VDBP* gene polymorphisms were not involved, thus limiting the interpretation of the pooled estimates.

In summary, we observed significant associations of *VDBP* gene rs7041 polymorphism with the risk of COPD and changes in circulating 25OHD concentrations. Importantly, under the rationale of Mendelian randomization, we found a causal relationship between genetically regulated 25OHD concentrations and COPD risk. Furthermore, our findings have highlighted the importance of employing the Mendelian randomization technique to pinpoint causal biomarkers and have provided clues regarding the causative pathways responsible for the biological regulation of 25OHD concentrations in COPD, thereby shedding new light in the physiology of this disease.

Data availability statement

The original contributions presented in the study are included in the article/Supplementary Material; further inquiries can be directed to the corresponding authors.

Author contributions

WN and ZZ planned and designed the study; WN and MY searched the literature, selected the articles, and abstracted the data; BP and QW performed data preparation and quality control; MY and WN analyzed the data and wrote the manuscript.

Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Background: Psoriasis is a common immune-mediated hyperproliferative skin dysfunction with known genetic predisposition. Gene–gene interaction (e.g., between HLA-C and ERAP1) in the psoriasis context has been reported in various populations. As ERAP1 has been recognized as a psoriasis susceptibility gene and plays a critical role in antigen presentation, we performed this study to identify interactions between ERAP1 and other psoriasis susceptibility gene variants.

Methods: We validated psoriasis susceptibility gene variants in an independent cohort of 5,414 patients with psoriasis and 5,556 controls. Multifactor dimensionality reduction (MDR) analysis was performed to identify the interaction between variants significantly associated with psoriasis in the validation cohort and ERAP1 variants. We then conducted a meta-analysis of those variants with datasets from exome sequencing, target sequencing, and validation analyses and used MDR to identify the best gene–gene interaction model, including variants that were significant in the meta-analysis and ERAP1 variants.

Results: We found that 19 of the replicated variants were identified with $p < 0.05$ and detected six single-nucleotide polymorphisms of psoriasis susceptibility genes in the meta-analysis. MDR analysis revealed that the best predictive model was that between the rs27044 polymorphism of ERAP1 and the rs7590692 polymorphism of IFIH1 (cross-validation consistency = 9/10, test accuracy = 0.53, odds ratio = 1.32 (95% CI, 1.09–1.59), $p < 0.01$).

Abbreviations: GWAS, genome-wide association studies; KNN, K-nearest neighbors; MAF, minor allele frequency; MDR, multifactor dimensionality reduction; PCR, polymerase chain reaction; SNP, single-nucleotide polymorphism; SNVs, single-nucleotide variations.

Conclusion: Our findings suggest that the interaction between ERAP1 and IFIH1 affects the development of psoriasis. This hypothesis needs to be tested in basic biological studies.

Introduction

Psoriasis is a common immune-mediated hyperproliferative skin dysfunction with known genetic predisposition that affects almost 125 million people worldwide (Armstrong and Read, 2020). Psoriasis morbidity rates range from 0.09% to 5.1% (Michalek et al., 2017), with major regional differences. The condition results from a combination of interacting genetic, environmental, and immunological factors (Myers et al., 2005; Mahil et al., 2015; Greb et al., 2016). Although progress has been made in the interpretation of its heredity, the pathogenesis of psoriasis remains unclear. Early correlation studies established that the genetic contribution to psoriasis is complex and multifactorial.

Since 2005, genome-wide association studies (GWASs) have been established as the most effective approach to the identification of genetic variations related to complex diseases via the use of a complex single-nucleotide polymorphism (SNP) map of the human genome to identify differences in allele frequency between patients and controls (Kruglyak, 2008; Zhang, 2012). Although GWASs have led to the robust identification of numerous susceptibility loci, they capture small proportions of estimated disease heritability; this issue is referred to as the “missing heritability” problem (Manolio et al., 2009; Eichler et al., 2010). Most correlational research involves the detection of SNPs in isolation, without examination of the mutual effects of their interaction, leading intricate reciprocities in the biosystem to be overlooked. With the accumulation of large amounts of genome data, further gene–gene interaction and association studies are essential to explore the biological pathways and pathogeneses of common diseases (Cordell, 2009).

Most common diseases are induced by the nonlinear interaction of numerous genetic and environmental factors. Complex diseases are always generated by gene–environment and gene–gene interactions, the latter of which can enhance their danger (Evans et al., 2006; Cordell, 2009). Many methods can be used to test for gene–gene interaction, including those involving logistic regression models, neural networks, and multifactor dimensionality reduction (MDR) (Cordell, 2009). The use of a traditional (e.g., logistic regression) model to detect multiple interactions at the same time imposes a huge computational burden due to the exponential increase in the number of interaction terms (Chattopadhyay and Lu, 2019). Although neural networks are considered good nonlinear models, they are prone to overfitting (Ritchie et al., 2003). MDR, developed by

Ritchie et al. (Ritchie et al., 2001) in 2001, is a non-parametric model-free method that can be applied directly in case-control and discordant sib-pair studies. It involves no *a priori* genetic model assumption, unlike other approaches (e.g., linear regression or generalized linear models); this enables the detection of any genetic interaction in relation to disease. With the division of samples into high- and low-risk groups, MDR enables the reduction of *n*-dimensional models to one-dimension and reduces type-I and-II errors. It is currently the most popular method for detection of gene–gene interaction, and it has been used to identify potential interaction loci in many diseases, including sporadic breast cancer (Ritchie et al., 2001), hypertension (Moore and Williams, 2002), type-2 diabetes mellitus (Cho et al., 2004), and the autoimmune diseases rheumatoid arthritis (Julià et al., 2007; Liu et al., 2011), systemic lupus erythematosus (Zhang et al., 2016), and ankylosing spondylitis (Evans et al., 2011).

Based on existing GWAS data (Zhang et al., 2009), our group has analyzed the interaction of various susceptibility genes (including HLA-IL12B, HLA-ICE (Zheng et al., 2011), HLA-C-ERAP1, and HLA-C-TRAF3IP2 (Yin et al., 2013) interactions) in the Han Chinese population. Such gene interactions, including those related to psoriasis, have been reported in different populations (Strange et al., 2010). ERAP1 has been reported as being related to psoriasis in multiple populations, and our group has genotyped and replicated its polymorphisms (Chen et al., 2022). In this study, we detected interactions of ERAP1 with other psoriasis susceptibility genes in the Han Chinese population.

Materials and methods

Sample collection

This study was conducted with data generated in our previous research—an exome sequencing study conducted with 781 patients with psoriasis and 676 controls and a targeted sequencing study conducted with 9,946 psoriasis cases and 9,906 controls (Tang et al., 2014). We performed a case-control study with an independent sample cohort consisting of 5,414 psoriasis cases and 5,556 controls to validate the psoriasis susceptibility genes. All patients and controls were of Han Chinese origin and had attended the First Affiliated Hospital of Anhui Medical University. The controls were healthy

volunteers without psoriasis, other autoimmune diseases, systemic disease, or a family history of psoriasis (in first-, second-, and third-degree relatives). Each patient was examined by medical professionals and diagnosed with psoriasis by two experienced dermatologists, with rigorous recording of clinical data to ensure their specificity and reliability. After obtaining informed consent, medical professionals collected peripheral blood samples from all patients and controls. This research was approved by the Ethics Committee of Anhui Medical University Committee and performed following Declaration of Helsinki guidelines.

Procedure

Genomic DNA was extracted from the participants' peripheral blood mononuclear cells. DNA concentrations and optical density ratios (A_{260}/A_{280}) were determined using a NanoDrop 1,000 spectrophotometer (Thermo Fisher Scientific, United States). The Sequenom MassArray system (Sequenom, United States) was used for SNP genotyping. We used 15 ng standardized genomic DNA per sample for subsequent genetic typing. We used multiplex polymerase chain reactions to amplify the genomic DNA and then performed site-specific monacyl elongation reactions to obtain products. The amplified products were purified with AgencourtAM SPRI XP microbeads (Beckman Coulter Life Sciences, United States). After desalination, the final products were transferred to a 384-element SpectrCHIP array (Applied Biosystems, United States). Alleles were detected with a matrix-assisted laser desorption ionization time-of-flight 70 mass spectrometer and analyzed using Massarray Typer 71 software (Sequenom, United States). In the independent cohort, validated SNPs were selected using the following terms: position within 500 kb of a psoriasis susceptibility gene tag, $p < 1.0 \times 10^{-4}$ in the exome sequencing and targeted sequencing studies, genotyping detection rate $>90\%$, and Hardy–Weinberg test $p > 1.0 \times 10^{-4}$ in controls.

Gene–gene interaction analysis

Based on our group's previous study (Chen et al., 2022), ERAP1 variants were genotyped and replicated in the present cohort. The statistical analysis was performed with PLINK 1.07 and a significance level of $p < 0.05$. Gene–gene interactions were analyzed with open-source MDR software (ver. 2.0 Beta 2; available from <http://sourceforge.net/projects/mdr>). As the MDR software requires complete datasets with no missing value, we replaced missing values with numbers that did not represent genotypes; the second method used was k -nearest neighbor estimation to fill in the missing values (k was equal to the square root of the number of SNPs) (Schwender, 2012).

Meta-analysis of GWAS discovery results

To expand the sample size and detect more gene–gene interactions, we conducted a meta-analysis of summary GWAS statistics from the exome sequencing ($n = 1,457$), targeted sequencing ($n = 19,007$), and validation ($n = 10,970$) cohorts. We performed the analysis with METAL (available from <http://www.sph.umich.edu/csg/abecasis/Metal/>), with the test statistics weighted by sample size. The genome-wide significance threshold was $p < 5 \times 10^{-8}$. We performed genomic correction of all results to control for potential inflation of the test statistics. Effector allele frequencies were tracked selectively across all files.

Results

Independent cohort validation

Of 39 SNPs selected for genotyping verification, 19 were significant ($p < 0.05$) in the independent cohort validation analysis. IFIH1 showed the strongest correlation with psoriasis (chr_163737871, $p = 6.52 \times 10^{-7}$, odds ratio (OR) = 0.81; chr2_163136771, $p = 1.72 \times 10^{-6}$, OR = 0.81; Table 1). Other validated psoriasis susceptibility genes were ERAP2 (5q15), IL18R1 (2q12.1), LTB (12p13.31), IL1RL1 (2q12.1), CARD14 (17q25.3), and SLC9A4 (2q12.1).

Gene–gene interaction study

The MDR analysis was conducted with the 19 SNPs showing significance in the replicated cohort and six ERAP1 SNPs. The rs27044 polymorphism of ERAP1 was the best single-locus model (CVC = 10, test accuracy = 0.52, OR = 1.32 (95% CI, 1.07–1.63), $p < 0.01$). The best predictive model (i.e., that with maximum testing accuracy) was that between the rs27044 polymorphism of ERAP1 and the rs7590692 polymorphism of IFIH1 (CVC = 9/10, test accuracy = 0.53, OR = 1.32 (95% CI, 1.09–1.59), $p < 0.01$; Table 2). In this model, high-risk genotypes were TT \times CC, TC \times GG, TC \times GC, TC \times CC, CC \times GC, and CC \times CC, and low-risk genotypes were TT \times GC, TT \times GG, and CC \times GG (Figure 1). Figures 2, 3 show measures of characterized epistatic of the models from the interaction analysis.

Results of the meta-analysis and MDR

In the meta-analysis, six of the 39 SNPs reached the genome-wide significance threshold ($p < 10^{-8}$). These SNPs were in IFIH1 (rs12479043, $p = 2.85 \times 10^{-15}$; rs7590692, $p = 1.57 \times 10^{-14}$), CARD14 (rs4889997, $p = 4.03 \times 10^{-12}$), GJB2 (rs72474224, $p = 8.22 \times 10^{-11}$), NFKB1 (rs3817685, $p = 4.24 \times 10^{-10}$), and ERAP2

The model with the maximum testing accuracy was considered the best model. MDR, multifactor dimensionality reduction; CVC, cross-validation consistency.

(rs2303208, $p = 7.50 \times 10^{-10}$; Table 3). In the MDR analysis of these SNPs and six SNPs of ERAP1, the best model was still that between the rs27044 polymorphism of ERAP1 and the rs7590692 polymorphism of IFIH1 (CVC = 9/10, test accuracy = 0.53, OR = 1.32 (95% CI, 1.09–1.59) $p < 0.01$).

Discussion

With the deep development of psoriasis-related genetic analysis, our group has generated systemic genomic data on psoriasis through exome and targeted sequencing. In this study, we verified the psoriasis susceptibility genes IFIH1 (2q24.3), ERAP2 (5q15), IL18R1 (2q12.1), LTBR (12p13.31), IL1RL1 (2q12.1), CARD14 (17q25.3), and SLC9A4 (2q12.1). We found that the most significant interaction was between

the rs27044 polymorphism of ERAP1 and the rs7590692 of IFIH1; this result was confirmed in the MDR analysis.

ERAP1 is an immune-related gene encoding multifunctional aminopeptidase that is induced by interferon- γ . It plays critical roles in antigen presentation and N-terminal peptide pruning to reach the best presenting size of the major histocompatibility complex I molecule. These molecules can present polypeptides containing 8–10 amino acids directly outside of cells, enhancing antigen presentation and T-cell activation in disease processes (Kochan et al., 2011). ERAP1 is more likely to be present in individuals carrying the HLA-C susceptibility allele, with the first and most important psoriasis susceptibility gene identified (Bowcock, 2005). A recent study revealed that ERAP1 causes psoriasis by affecting HLA-C production via melanocyte autoantigens (Arakawa et al., 2021). Thus, it may cause psoriasis lesions by interacting with HLA-C.

ERAP1 has been related to psoriasis in Chinese (rs151823) (Sun et al., 2010) and European (rs27524) (Strange et al., 2010) populations. In a meta-analysis of nine case-control studies, the

rs27044 polymorphism of ERAP1 was associated significantly with psoriasis (Wu and Zhao, 2021). This gene has also been associated with ankylosing spondylitis (Tsui et al., 2010), Behcet's disease, multiple sclerosis, and inflammatory bowel disease (Reeves and James, 2018).

We replicated IFIH1 in our independent sample cohort with $p = 6.52 \times 10^{-7}$. IFIH1 encodes MDA5, an innate pattern recognition receptor. MDA5 is a cytoplasmic sensor of picornavirus nucleic acids that triggers a cascade of antiviral responses, including the induction of type I interferons and pro-inflammatory cytokines. Once it is bound to pathogen-like viral RNA, activated MDA5 interacts with mitochondrial antiviral-signaling proteins and then phosphorylated interferon regulatory factors (IRFs) 3 and 7. Dimers are formed by phosphorylated IRF-3 and -7 and move into cell nuclei to stimulate the secretion of type 1 interferon (IFN1) (Brisse and Ly, 2019). IFN1 mediates autoimmune responses to invaders such as viruses. MDA5 has been observed to significantly increase psoriatic plaques and keratinocytes, and its overexpression acts as a negative regulator for the differentiation of calcium-induced keratinocytes in psoriatic skin lesions (Hong et al., 2021). IFIH1 has been related to psoriasis in a European population (rs17716942) (Strange et al., 2010), and its rs35667974 and rs10930046 polymorphisms were found to have protective effects against psoriasis in a white North American population (Li et al., 2010). In addition, evidence supports the involvement of IFIH1 SNPs in inflammatory diseases such as type 1 diabetes (Nejentsev et al., 2009), inflammatory bowel disease (Cananzi et al., 2021), and dermatomyositis (Kurtzman and Vleugels, 2018).

Our MDR analysis revealed a significant association between ERAP1 and IFIH1, suggesting that the presence of the ERAP1 rs27044 polymorphism affects the expression of the IFIH1 rs7590692 polymorphism. In an *in vitro* experiment (Aldhamen et al., 2013), increased levels of proinflammatory cytokines such as tumor necrosis factor (TNF)- α were observed in ERAP1-knockout mice, suggesting that the lack of ERAP1 expression induces increased autoimmune activity. TNF- α , a cytokine commonly elevated in patients with psoriasis, promotes the transcription of MDA5 and RIG-I in keratinocytes (Kitamura et al., 2007; Racz et al., 2011). Taken together, these molecular biological findings suggest that ERAP1 might regulate the expression of IFIH1, but more basic biological studies are needed to determine how this gene interaction affects psoriasis.

This study has several limitations. The results provide evidence of correlations between gene-gene interactions and psoriasis but no information about the mechanisms of resulting effects, and the accuracy of the best model was not high. We will carry out further basic biological studies to verify this result. In addition, the study was conducted with data from a Han Chinese population; similar studies need to be conducted with data from other ethnic groups.

In summary, we screened for interactions between genes that affect psoriasis susceptibility and found that the most significant interaction was between the rs27044 polymorphism of ERAP1 and the rs7590692 polymorphism of IFIH1. Psoriasis

is a multifactorial autoimmune disease with many genetic contributions. Although our comprehension of the genetic mechanisms underlying it has increased and the interaction of susceptibility genes has been identified based on SNPs, many questions remain. A better understanding of how these gene interactions affect the development of psoriasis, generated from basic biological studies, may provide answers to these questions.

Data availability statement

The datasets presented in this study can be found in online repositories. The names of there pository/repositories and accession number(s) can be found below: Zenodo with accession 7260050—(<https://doi.org/10.5281/zenodo.7260050>).

Ethics statement

The studies involving human participants were reviewed and approved by the Clinical Research Ethics Committee of Anhui Medical University. The patients/participants provided their written informed consent to participate in this study.

Author contributions

LS and WW conceived and designed the research. CZ wrote this manuscript. QQ and YL were responsible for selecting blood samples and extracting DNA. CZ, QQ, and YL contributed equally to this work. XZ, WC, BL, and QZ performed data

analysis. All authors contributed to the study and approved the final manuscript.

Funding

This study was supported by grants from the Anhui Institute of Translation Medicine (ZHY 2020A005) and the University Synergy Innovation Program of Anhui Province (GXXT-2020-064).

Acknowledgments

We thank the patients and their families who contributed to this study.

Idiopathic pulmonary fibrosis (IPF) is a chronic progressive interstitial lung disease of unknown etiology, characterized by diffuse alveolitis and alveolar structural damage. Due to the short median survival time and poor prognosis of IPF, it is particularly urgent to find new IPF biomarkers. Previous studies have shown that basement membranes (BMs) are associated with the development of IPF and tumor metastasis. However, there is still a lack of research on BMs-related genes in IPF. Therefore, we investigated the expression level of BMs genes in IPF and control groups, and explored their potential as biomarkers for IPF diagnosis. In this study, the GSE32537 and GSE53845 datasets were used as training sets, while the GSE24206, GSE10667 and GSE101286 datasets were used as validation sets. In the training set, seven immune biomarkers related to BMs were selected by differential expression analysis, machine learning algorithm (LASSO, SVM-RFE, Randomforest) and ssGSEA analysis. Further ROC analysis confirmed that seven BMs-related genes played an important role in IPF. Finally, four immune-related Hub genes (*COL14A1*, *COL17A1*, *ITGA10*, *MMP7*) were screened out. Then we created a logistic regression model of immune-related hub genes (IHGs) and used a nomogram to predict IPF risk. The nomogram model was evaluated to have good reliability and validity, and ROC analysis showed that the AUC value of IHGs was 0.941 in the training set and 0.917 in the validation set. Pan-cancer analysis showed that IHGs were associated with prognosis, immune cell infiltration, TME, and drug sensitivity in 33 cancers, suggesting that IHGs may be potential targets for intervention in human diseases including IPF and cancer.

KEYWORDS

idiopathic pulmonary fibrosis, basement membrane, immune, pan-cancer, interstitial lung disease

1 Introduction

Idiopathic pulmonary fibrosis (IPF) is a chronic progressive interstitial lung disease of unknown etiology (Richeldi et al., 2017). Its pathological features are diffuse alveolitis and alveolar structural damage, eventually forming honeycomb lung (Wolters et al., 2014). The clinical symptoms of IPF include dry cough, fatigue, and progressive exertional dyspnea. IPF is a rare

disease, but its incidence is increasing and is more common in elderly male patients (Maher et al., 2021; Kondoh et al., 2022). Although disease progression varies greatly among individuals, the median survival after diagnosis is less than 3–5 years. Currently, treatment options for patients with IPF remain limited. Anti-fibrotic drugs (Pirfenidone and Nintedanib) have been approved to treat IPF, but they only slow the decline in lung function in IPF patients and do not improve survival (King et al., 2014; Richeldi et al., 2014). These drugs can also cause gastrointestinal adverse reactions, which limits their widespread use to some extent (Bargagli et al., 2019). At present, lung transplantation remains the only effective treatment. Unfortunately, not all patients are suitable for transplant, and complications following the transplant place a huge burden on patients.

Basement membranes (BMs) are a specialized form of extracellular matrix found in various organs of the human body, providing structural support for epithelium, endothelium, muscle, adipocytes, schwann cells, and axons (Mak and Mei, 2017). BMs are mainly composed of laminin and type IV collagen, which are linked together by nicotylsaccharide and heparan sulfate proteoglycans to form different BMs in various tissues (Kruegel and Miosge, 2010). BMs can direct cell polarity, differentiation, migration and survival. For example, BMs can control epithelial growth and differentiation during embryonic development (Kyprianou et al., 2020). In cancer, the breakdown of the basement membrane promotes metastasis (Banerjee et al., 2022). Variations in the BMs gene are closely associated with many human diseases (Horton and Barrett, 2021; Wilson, 2022). BMs can mark the pathway of cell migration and epithelialization during tissue repair (Vracko, 1974; Rousselle et al., 2019). Changes in BMs homeostasis can lead to abnormal ECM aggregation and fibrosis (Wilson, 2020). Alveolar BMs promote gas exchange between alveoli and capillaries and regulate the function of cytokines and growth factors (West and Mathieu-Costello, 1999). The integrity of BMs maintains the normal lung structure and is critical for restoring alveolar epithelial homeostasis after lung injury (Strieter and Mehrad, 2009). However, a loss of alveolar and capillary BMs integrity was observed in IPF, suggesting that BMs are involved in IPF genesis (Chen et al., 2016).

Increasing evidence supports the important role of immune response in IPF. On the one hand, damage to lung epithelial cells leads to the production of pro-inflammatory cytokines such as IL-1 and IL-6 in M1 alveolar macrophages (Huang et al., 2018). These cytokines play an important role in host resistance to pathogen invasion. Inhibition of TNF- α secretion can alleviate bleomycin-induced pulmonary fibrosis and collagen deposition (Matsuhira et al., 2020). On the other hand, under chronic inflammatory conditions, Th2 cells secrete cytokines to gradually transform pro-inflammatory M1 macrophages into pro-fibrotic M2 macrophages (Shapouri-Moghaddam et al., 2018). M2 macrophages secrete multiple chemokines and activate Wnt/ β -catenin signaling pathways leading to fibroblast activation, myofibroblast differentiation and extracellular matrix remodeling (Wynn and Vannella, 2016). Inhibition of Wnt/ β -catenin signaling attenuates M2 macrophage-induced myofibroblast differentiation and bleomycin-induced pulmonary fibrosis (Hou et al., 2018). Another study found that vaccination inhibited M2 macrophage production and fibrocyte recruitment in bleomycin-induced pulmonary fibrosis (Collins et al., 2012). Moreover, the importance of immune responses in IPF has been confirmed by genetic studies, such as DEP domain

containing MTOR interacting protein (*DEPTOR*) increase the risk or susceptibility of IPF (Allen et al., 2020).

In this article, we aim to explore the immune markers associated with BMs in IPF and construct a nomogram model to predict the risk of IPF in patients. Increased evidence suggests that IPF is closely linked to cancer (Ballester et al., 2019; Tzouveleakis et al., 2019). However, little is known about the relationship between IPF and cancer. Therefore, we conducted an in-depth analysis of the role of BMs-related immune biomarkers in pan-cancer to explore the common pathogenesis of IPF and cancer, and to find potential therapeutic targets for patients with IPF and cancer. In Figure 1, you can see the workflow chart.

2 Materials and methods

2.1 Data download and processing

We obtained 222 BMs related genes from previous studies (Jayadev et al., 2022). We obtained datasets numbered GSE32537, GSE53845, GSE24206, GSE10667 and GSE101286 from the GEO database (<https://www.ncbi.nlm.nih.gov/geo/>). The GSE32537, GSE53845 datasets were used as training set. Datasets GSE24206, GSE10667 and GSE101286 were used as validation sets for independent external validation. The main features of the five datasets were shown in Table 1. Datasets were merged after identity document transformation. The original data was normalized through R software “sva” package, followed by classification of the datasets into two categories: IPF and control groups. Finally, we evaluated the quality of the dataset using principal component analysis and plotted the PCA plot via R software “ggplot2” package.

2.2 Identification of differentially expressed genes in BMs

We screened differentially expressed genes (DEGs) through R software “limma” package, filter condition for $p < 0.05$ and $|\log_2FC| > 1$. A volcano map was drawn through the “ggplot2” package of R software to show DEGs. The “VennDiagram” package in R was used to obtain the intersection of BMs-related genes and DEGs, and the differentially expressed genes of basement membranes (BMDEGs) were obtained.

2.3 Protein–protein interaction (PPI) and enrichment analysis of BMDEGs

We visualized the PPI network of BMDEGs via the STRING database and performed GO, KEGG, and DO enrichment analyses of BMDEGs via the “ClusterProfiler” and “DOSE” packages of R software.

2.4 Three machine learning algorithms for screening disease candidate genes

We used LASSO, SVM-RFE and RandomForest machine learning algorithms to screen disease candidate genes. LASSO

FIGURE 1
The workflow chart of our study.

analysis was performed using 10-fold cross-validated penalty parameters *via* the “glmnet” package of R software. The minimal bimomial deviation was used to determine the optimal penalty parameter lambda. SVM-RFE algorithm detects the points with the minimum cross-validation error through the “e1071”, “kernlab” and “caret” packages in R software to screen disease candidate genes. The RandomForest algorithm uses the “randomforest” package of R software to screen disease candidate genes. The Venn diagram visualizes disease candidate genes obtained from the results of three machine learning algorithms.

2.5 Validation of disease candidate genes

To understand the specificity and sensitivity of disease candidate genes for IPF diagnosis, we draw the receiver operating characteristic (ROC) curve through the “pROC” package of R software. Results were presented in the form of area under the curve (AUC). If the AUC of candidate genes was greater than 0.6, we believed that it had diagnostic significance for IPF. Disease candidate gene expression in the IPF and control groups was shown in the box plot.

2.6 Analysis of immune infiltration

We performed correlation analysis of immunity through the “corrplot” package of R software and plotted the correlation heatmap. R software “ggpubr” and “reshape2” packages were used to analyze the differential expression of immune cells and immune functions in IPF and control groups. Spearman correlation analysis was conducted through the “psych” and “ggcorrplot” packages of the R software to analyze the correlation between disease candidate genes and immunity. The screening criteria for IPF immune-related hub genes (IHGs) were more than 1/2 immune infiltration and the correlation coefficient was greater than 0.2.

2.7 Establishment and validation of IHGs risk model

We constructed the nomogram of IHGs and plotted the calibration curve to determine the reliability of the nomogram through the “rms” package of R software. ROC curves were

TABLE 1 An overview of the main features of the dataset used in this study.

Dataset	Platform	IPF	Normal	Publication years	Used for
GSE32537	GPL6244	167	50	2013	DEGs analysis
GSE53845	GPL6480	40	8	2014	DEGs analysis
GSE24206	GPL570	17	6	2011	Model validation
GSE10667	GPL4133	31	15	2009	Model validation
GSE101286	GPL6947	12	3	2017	Model validation

plotted to assess the accuracy of IHGs in diagnosing IPF *via* the “ROCR” package of R software.

2.8 Differential analysis of IHGs in human cancer

We downloaded tumor transcriptome data, clinical data, immune subtype data, mutation data and stemness score (RNAss and DNAss) from the UCSC Xena database (<https://xenabrowser.net/>). The expression levels of IHGs in 33 tumor and adjacent samples were extracted using the “limma” package of R software. Then, we retained tumor types with more than 5 paracancer tissues, and analyzed the expression of IHGs in tumors and paracancer tissues through the “ggpubr” package of R software.

2.9 Survival analysis of IHGs in pan-cancer

COX regression analysis was conducted through the “survival” package of R software to determine whether IHGs expression was correlated with the survival time and survival status of cancer patients, and the results were presented in forest plots. Survival analysis was performed through the “survival” and “surminer” packages of R software to determine whether IHGs expression was linked with the prognosis of tumor patients.

2.10 Mutation analysis of IHGs in pan-cancer

Tumor mutation burden (TMB) and microsatellite instability (MSI) is specific indicators for predicting immunotherapy in cancer patients. Therefore, we used the “fmsb” package of R software to plot radar maps of TMB and MSI to determine the correlation between IHGs expression and 33 types of tumors.

2.11 Tumor microenvironment (TME) and tumor stemness analysis

We calculated the immune score, stromal score, and estimated score for each sample in the tumor using the “estimate” package of R software. The correlation between IHGs expression and purity in

33 tumors was analyzed by Spearman correlation analysis. The relationship between IHGs expression and tumor stemness was determined by the “corrplot” package of R software.

2.12 Immune analysis of IHGs in pan-cancer

Immune subtypes including C1(Wound Healing), C2(IFN γ Dominant), C3(Inflammatory), C4 (lymphocyte Depleted), C5 (M2 macrophages Dominant), C6 (TGF- β Dominant) subtypes. Previous studies have shown that among the six immune subtypes, C4 and C6 are associated with lower survival rates, while C3 and C5 are the opposite (Tamborero et al., 2018). The relationship between IHGs expression and immune subtypes was analyzed by the “limma”, “ggplot2” and “reshape2” packages of R software. The correlation between IHGs expression and immune checkpoints was completed by Pearson correlation analysis. Finally, we investigated the correlation between IHGs expression in tumors and 21 types of immune cells using TIMER2.0 database (<http://timer.cistrome.org/>).

2.13 Enrichment analysis

We used the GeneMANIA database (<http://genemania.org/>) to predict and visualize genes that function similar to IHGs. The Metascape website (<https://metascape.org/>) was used to analyze the functions in which genes may be involved.

2.14 Drug sensitivity analysis of IHGs in pan-cancer

We downloaded drug sensitivity data for 60 human cancers from the CellMiner websites (<https://discover.nci.nih.gov/cellminer/>) and screened 263 FDA-approved or clinical trial drugs for this study. The relationship between IHGs expression and drugs was analyzed by Pearson correlation analysis.

2.15 Statistical analysis

Statistical tests were performed using R software (version 4.1.3). For all statistical analyses, $p < 0.05$ was considered statistically significant (“***”, “**”, “*”, “ns” are “ $p < 0.001$ ” “ $p < 0.01$ ” “ $p <$

0.05” “no significance”). Relevant scripts and supported data can be seen on the Github website (<https://github.com/fuchenkun/Basement-membranes>).

3 Results

3.1 Screening for BMDEGs of IPF

We combined GSE32537, GSE53845 datasets and corrected the batch effects for subsequent analyses (Figures 2A, B). 253 DEGs were screened, of which 158 genes were over-expressed and 95 genes were under-expressed. The results of the DEGs were presented as a volcano map (Figure 2C). A Venn diagram was also created, which showed that 13 BMDEGs, of which 12 were upregulated and 1 downregulated (Figure 2D).

3.2 Protein interaction network and enrichment analyses of BMDEGs

We constructed a protein interaction network for BMDEGs (Figure 2E). Then we performed enrichment analyses to better understand the functions, pathways, and diseases that BMDEGs might be involved in. As shown in Figure 2F, our results indicated that biological processes were mainly related to the structure of extracellular matrix, collagen catabolic processes, and responses to mechanical stimulus. The cellular components mainly involved extracellular matrix, basement membrane and endoplasmic reticulum. Extracellular matrix structural constituent, heparin binding, glycosaminoglycan binding, sulfur compound binding and extracellular matrix structural constituent conferring tensile strength were significantly enriched in molecular functions. The KEGG analysis revealed that BMDEGs tended to be enriched in the

following terms: extracellular matrix organization, extracellular structure organization, external encapsulating structure organization, cell–substrate adhesion and response to mechanical stimulus (Figure 2G). Moreover, DO analysis found that BMDEGs were specifically enriched in IPF and were also associated with endocrine disorders, reproductive system diseases, and cancer (Figure 2H).

3.3 Screening and validation for IPF diagnostic markers

We further used machine learning algorithms to screen disease candidate genes from BMDEGs. LASSO regression analysis selected

11 genes (Figure 3A), the SVM-RFE algorithm identified eight genes (Figure 3B), and RandomForest screened 11 genes (Figure 3C). Finally, through the gene intersection obtained by the three algorithms, seven disease candidate genes (*COL14A1*, *COL17A1*, *HMCN1*, *ITGA10*, *MMP7*, *OGN* and *ROBO2*) were identified (Figure 3D). Then we analyzed the expression of seven disease candidate genes in the training group and validated them using external datasets. Validation group dataset eliminates batch effect for subsequent analysis (Supplementary Figure S1). As presented in Figure 3E, the boxplot showed that seven disease candidate genes were significantly upregulated in IPF groups and 1 candidate gene was significantly downregulated in IPF groups. We saw the same results in the validation dataset, but *ROBO2* was not statistically significant (Figure 3F). We further performed ROC analysis to

FIGURE 4

Immune infiltration analysis and establishment of IPF risk model. (A) Correlation heatmap of immune cells. (B) Immune function related heatmap. (C) Difference of immune cell expression between IPF and control groups. (D) Difference of immune function expression between IPF and control group. (E) Heatmap of correlation between IHGs expression and immune infiltration. (F) IHGs predicts the occurrence of IPF in training set. (G) IHGs predicts the occurrence of IPF the validation set.

examine the diagnostic efficacy of seven disease candidate genes for IPF. The results suggest that the seven disease candidate genes have diagnostic value in distinguishing IPF groups from control groups: *COL14A1* (AUC = 0.964), *COL17A1* (AUC = 0.915), *HMCN1* (AUC = 0.961), *ITGA10* (AUC = 0.946), *MMP7* (AUC = 0.937), *OGN* (AUC = 0.894) and *ROBO2* (AUC = 0.856) (Supplementary Table S1). Similarly, we evaluated the diagnostic efficacy of seven disease candidate genes for IPF in the validation group dataset using ROC analysis. The results indicated that AUCs of the disease candidate genes were *COL14A1* (AUC = 0.881), *COL17A1* (AUC = 0.949), *HMCN1* (AUC = 0.813), *ITGA10* (AUC = 0.707), *MMP7* (AUC = 0.910), *OGN* (AUC = 0.719) and *ROBO2* (AUC = 0.600) (Supplementary Table S2). In conclusion, the AUC values of *COL14A1*, *COL17A1*, *HMCN1*, *ITGA10*, *OGN* and *MMP7* in the training dataset and validation dataset were all greater than 0.7. These results suggest that the candidate genes are closely related to IPF and have the potential to be used as biomarkers of IPF and indicators to evaluate the efficacy of patients.

3.4 Immune infiltration analysis and IHGs screening

We used the ssGSEA algorithm to evaluate immune infiltration in 265 samples (Supplementary Figure S2). In the correlation analysis of immune cells, the positive correlation between Tfh cells and B-cell was the strongest, and the correlation coefficient was 0.8. The negative correlation between Tfh cells and NK cells was the strongest, and the correlation coefficient was -0.3 (Figure 4A). Interestingly, we did not observe a negative correlation for immune function, whereas there was a positive correlation ($r = 0.8$) between T-cell co inhibition and APC co inhibition (Figure 4B). For immune cells, the expression of aDCs, B-cell, DCs, iDCs, Mast cells, T helper cells, Tfh and Th1 cells were increased in IPF, while the expression of neutrophils, NK cells, pDCs, Th2 cells and Treg cells were decreased (Figure 4C). For immune function, Check point, HLA, Inflammation promoting, T-cell co stimulation and Parainflammation were over-expressed in IPF, while T-cell co inhibition and APC co inhibition were underexpressed in IPF (Figure 4D). Finally, four IHGs were screened by correlation analysis, including *COL14A1*, *COL17A1*, *ITGA10* and *MMP7* (Figure 4E). These results suggest that the activation of multiple immune cells and the coordination of immune functions are important in the pathogenesis of IPF.

3.5 Construction and validation of IPF risk model

We created a logistic regression model of IHGs and used a nomogram to predict IPF risk (Figure 4F). The calibration curve used to evaluate the risk nomogram of IPF patients showed good consistency in this study. The results showed that the AUC of the training data set was 0.941, indicating that our model had good predictive ability. In order to further verify the prediction effect of our model, we used independent external validation dataset to verify (Figure 4G). The results showed that the calibration curve also showed good consistency in the training dataset. The AUC value in

the validation dataset was 0.917, which also shows that our model had good predictive ability. Moreover, The C index also shows that our model had good predictive power. The C index was 0.941 (95% CI: 0.917–0.965) in the training dataset and 0.917 (95% CI: 0.840–0.994) in the validation dataset.

3.6 The expression level of IHGs in pan-cancer

To determine whether there are differences in the expression of IHGs in tumors, mRNA expression levels of IHGs in normal and tumor tissues were analyzed. As shown in Figure 5A, the expression of *MMP7* in IHGs was relatively high, while the expression of *ITGA10* was the lowest. The expression of IHGs in different cancer types is also quite different (Figure 5B). Overall, *COL14A1*, *COL17A1*, and *ITGA10* tended to be downregulated in most tumors, while *MMP7* tended to be upregulated in most tumors. Correlation analysis showed that *ITGA10* was weakly positively correlated with *COL14A1*, and weakly negatively correlated with *MMP7* and *COL17A1* (Figure 5C). Although there is a correlation between IHGs, the correlation coefficient value is between -0.15 and 0.23, which proves that the correlation is weak or negligible. *COL14A1* was highly expressed in 1 tumor and lowly expressed in 15 tumors (Figure 5D). *COL17A1* was significantly upregulated in seven tumors, while significantly downregulated in eight tumors (Figure 5E). *ITGA10* expression was increased in six tumors and decreased in eight tumors (Figure 5F). *MMP7* expression was higher in 12 tumors and lower in four tumors (Figure 5G).

3.7 Pan-cancer survival analysis of IHGs

Based on the results of differential analysis, we used forest maps and survival curves to further understand whether IHGs expression was linked with tumor prognosis (Figure 5H). Cox regression analysis revealed that increased *COL14A1* expression was a negative factor affecting KIRP, LGG, BLCA, STAD and OV, while a positive factor affecting ACC. Increased expression of *COL14A1* was related to shorter overall survival (OS) in BLCA, KIRP, LGG and UVM, whereas decreased expression of *COL14A1* was related to shorter OS in ACC and LAML (Figures 6A–F). As shown as Figures 6G–I, Cox regression analysis revealed that *COL17A1* over-expression was an adverse factor for PAAD and SKCM, but a favourable factor for BRCA. Overexpression of *COL17A1* was linked with poorer OS in PAAD and SKCM, whereas increased *COL17A1* expression predicted favorable OS in LGG. As seen as Figures 6J–R, Cox regression analysis found that the increased expression of *ITGA10* was a negative factor for LGG, SARC and KICH, and a positive factor for SKCM and BRCA. High *ITGA10* expression was related to shorter OS for KIRP, LGG, MESO, OV, SARC, STAD, THCA, and longer OS for BRCA and SKCM. According to Figures 6S–Y, Cox regression analysis revealed that high expression of *MMP7* was an adverse factor for PAAD, ACC, LAML, KIRC, LIHC and SKCM, while high expression of *MMP7* was a beneficial factor for BRCA. Survival analysis showed that patients with increased *MMP7* expression in ACC, KIRC, LAML, LGG, LIHC, MESO, PAAD had shorter OS.

FIGURE 5 Expression of IHGs in Human Cancer. **(A)** Boxplots of IHGs expression levels in cancer. **(B)** Heatmap of IHGs expression levels in different cancer types and adjacent tissues. **(C)** Positive (blue) and negative (red) correlations between IHGs. Expression of *COL14A1*(D), *COL17A1*(E), *ITGA10*(F) and *MMP7*(G) in different tumor types and adjacent tissues. **(H)** Forest plot shows the relationship between IHGs expression and OS in 33 tumors.

FIGURE 6

Relationship between IHGs expression and prognosis of different tumors. OS survival curves for *COL14A1* in six tumors: (A) ACC, (B) BLCA, (C) KIRP, (D) LAML, (E) LGG, (F) UVM. OS survival curves for *COL17A1* in 3 tumors: (G) LGG, (H) PAAD, (I) SKCM. OS survival curves for *ITGA10* in 9 tumors: (J) BRCA, (K) KIRP, (L) LGG, (M) MESO, (N) OV, (O) SARC, (P) SKCM, (Q) STAD, (R) THCA. OS survival curves for *MMP7* in 7 tumors: (S) ACC, (T) KIRC, (U) LAML, (V) LGG, (W) LIHC, (X) MESO, (Y) PAAD.

3.8 Correlation of IHGs expression with TME and tumor stemness

TME is closely related to tumorigenesis and tumor cells escaping the immune system. The therapeutic effect and clinical prognosis of tumor are also correlated with TME. Therefore, the correlation between IHGs expression and tumor purity was assessed to understand whether IHGs are involved in tumor immunity. Overall, IHGs expression was positively related to stromal scores, with *COL14A1* having the strongest correlation with stromal score (Figure 7A). In terms of immune score, IHGs expression was positively correlated with CHOL, KICH, LIHC, and PCPG, etc., (Figure 7B). This suggests that IHGs have similar effects in the TME. Furthermore, we also evaluated the correlation between IHGs expression and tumor stemness score to understand the effect of IHGs expression on tumor differentiation. We found that IHGs were negatively related to RNAss in most tumors (Figure 7C). In contrast, it

was positively related to DNAss in KIRC, KIRP, THYM and UVM (Figure 7D). These results suggest that the higher the expression of IHGs, the weaker the stemness score and the higher the degree of tumor differentiation.

3.9 Correlation of IHGs expression with immune subtype and immune checkpoints

Our results showed that *COL14A1*, *COL17A1*, and *MMP7* were over-expressed in the C1, C2, and C6 subtypes, and *ITGA10* was over-expressed in the C5 and C6 subtypes (Figure 7E). The high expression of *COL14A1*, *COL17A1* and *MMP7* was closely related to C1, C2 and C6 subtypes, indicating that these three genes may have carcinogenic effects. Moreover, we observed a significant correlation between IHGs expression and immune checkpoint genes in different

tumor types. Specifically, the results revealed that *COL14A1* was positively related to immune checkpoints in most tumors except MESO, OV, SARC, TGCT, THCA, THYM, UCEC, UCS, and UVM (Figure 7F). *COL17A1* was significantly related to immune checkpoints in most tumors except ACC, CHOL, DLBC, UCS, and UVM (Figure 7G). *ITGA10* was positively related to more than 30 immune checkpoint genes in COAD, ESCA, KICH, HNSC and LUSC (Figure 7H). In addition to CESC, CHOL, COAD, SARC, SKCM, and UVM, *MMP7* was closely related to immune checkpoint genes (Figure 7I). These results indicate that IHGs expression is closely related to immune checkpoint genes, suggesting that IHGs may play a vital role in mediating tumor immune patterns.

3.10 Immune cell infiltration analysis of IHGs in pan-cancer

We analyzed the correlation between tumor infiltrating immune cells and IHGs expression by TIMER2.0 to understand whether IHGs participated in tumor immune infiltration. We found that *COL14A1* was positively related to CAF, DCs, Endo, HSC, Macrophage, Monocyte and Tregs (Figure 8A). *COL17A1* was negatively related to most immune cells in HNSC, LUSC and ESCA (Figure 8B). *ITGA10* was positively related to CAF, Endo, HSC, neutrophils and Tregs in most tumors (Figure 8C). *MMP7* was positively related to CAF, DCs, Macrophage and Monocyte in most tumors (Figure 8D). Compared with *COL17A1*, *ITGA10* and *MMP7*, *COL14A1* had a higher correlation coefficient with infiltrating cells.

These results suggest a potential mechanism by which IHGs have different prognostic value in different tumors.

3.11 TMB and MSI analysis of IHGs in human cancers

The more frequent the mutation of tumor cells, the more new antigens produced, making them more susceptible to immunotherapy (Gryfe et al., 2000; Samstein et al., 2019). Herein, we investigated the correlation between IHGs expression with TMB, MSI. We found that *COL14A1/ITGA10/MMP7* was positively related to TMB in LGG, and negatively related to TMB in STAD, LUSC, LUAD, LIHC, HNSC and BLCA (Figures 8E–H). As for MSI, *COL14A1/ITGA10/MMP7* expression was negatively correlated with STAD (Figures 8I–L). Although these correlations are important to guide immunotherapy in cancer patients, the correlation coefficients between IHGs expression and TMB and MSI did not exceed 0.6 in all tumor types, suggesting that IHGs are unlikely to affect tumorigenesis by participating in gene modification processes and are insufficient to independently predict patient response to immunotherapy.

3.12 Functional enrichment analysis of IHGs in pan-cancer

We utilized GeneMANIA to screen genes associated with IHGs for comprehensive functional and pathway analysis of IHGs. Finally,

we constructed an IHGs-centric PPI network consisting of 24 genes (Figure 9A). Metascape significantly enriched items include Extracellular matrix organization, ECM-receptor interaction, Degradation of the extracellular matrix, Integrin cell surface interactions, epidermis development, PID AJDISC 2PATHWAY, ECM proteoglycans, response to wounding, Proteoglycans in cancer, Wnt signaling pathway and pluripotency, Type I hemidesmosome assembly, Immunoregulatory interactions between a Lymphoid, appendage development and response to growth factor (Figure 9B).

3.13 Drug response analysis of IHGs

We further explored whether the expression of IHGs has guiding significance for clinical medication. Among 263 drugs (FDA approved or clinical trials), we found that the sensitivity of 55 drugs was significantly correlated with IHGs expression levels.

As presented in Figure 9C, we show the top 20 drugs most significantly associated with IHGs. The upregulated expression of IHGs was associated with increased sensitivity to Afatinib, Pentostatin, Gefitinib, kahalide f, Lapatinib, Vandetanib, Ibrutinib, Erlotinib, and okadaic acid, and decreased sensitivity to Pyrazoloacridine, AT-13387, Pazopanib, Vincristine, Lapachone, Etoposide, Lomustine, Paclitaxel, Epothilone B, and Pipamperone. Overall, we found that IHGs expression was associated with treatment response, suggesting that IHGs may be involved in tumor drug resistance.

4 Discussion

In this study, we screened 13 BMDEGs using bioinformatics methods, among which 12 genes were over-expressed and 1 gene was lowly expressed. Subsequent GO enrichment analysis showed

that all BMDEGs were mainly related to extracellular matrix tissue and collagen catabolic process, while KEGG enrichment analysis showed a certain correlation with Notch signaling pathway. Based on three machine learning algorithms, we screened seven disease candidate genes. Using external datasets, it was confirmed that

COL14A1, *COL17A1*, *HMCN1*, *MMP7*, *OGN* and *ROBO2* were highly expressed in IPF, while *ITGA10* was lowly expressed in IPF. ROC curve analysis further confirmed that all disease candidate genes have diagnostic value in IPF, suggesting that they may have potential application prospects in the treatment of

IPF. The findings suggest their potential usage for diagnostic value in IPF since they are highly expressed in IPF. The findings will eventually lead to future studies about the potential role of their involvement in IPF, and if their roles are confirmed, the potential application prospects in the treatment of IPF are likely to be evaluated. Finally, four IHGs (*COL14A1*, *COL17A1*, *ITGA10*, *MMP7*) were screened out. We then construct a logistic regression model of IHGs and use a nomogram to predict IPF risk. The AUC of the training set was 0.941, and that of the verification set was 0.917. It shows that our model has good predictive ability, and these four genes are potential biomarkers of IPF. Our study provides a theoretical basis for studying the role of BMs-associated immune biomarkers in the pathogenesis of IPF, and provides promising research suggestions for subsequent studies.

In pan-cancer, the expression of IHGs was significantly different across cancers compared to comparable normal tissues. *COL14A1* was significantly downregulated in almost all cancer types. *COL17A1*, *ITGA10* and *MMP7* showed high intertumoral heterogeneity between tumor tissues and adjacent tissues. These results suggest that IHGs are a potential cancer biomarker.

Our study found that *COL14A1* was an adverse factor for KIRP, LGG, BLCA, STAD and OV, and a favourable factor for ACC. However, there is a lack of relevant studies to support the effect of *COL14A1* on the prognosis of these cancers, and more studies are needed to prove this. *COL14A1* encodes the alpha chain of type XIV collagen, which is linked with mature collagen fibers (Schuppan et al., 1990). It has been reported that *COL14A1* can affect arterial remodeling and participate in the occurrence of cardiovascular diseases (Weis-Müller et al., 2006; Guay et al., 2015). To our knowledge, there is a lack of literature on the role of *COL14A1* in IPF. When compared cancer with or without metastasis, it seems that further decrease of *COL14A1* has better outcome, but, this has to be tested in a larger scale to validate (Goto et al., 2015; Jiang et al., 2022). *COL14A1* methylation is an unfavorable prognostic factor for renal cell carcinoma, and low *COL14A1* expression seems to promote tumorigenesis of renal cell carcinoma (Morris et al., 2010). It seems that *COL14A1* is increased in IPF, while it is decreased in cancer. The differential expression of *COL14A1* may indicate the critical signaling that differentiates IPF - a disease with non-stopping fibroblast growth, from cancer - a disease with non-stopping malignant cell growth. Therefore, our studies suggest the critical and differentiating signaling may involve *COL14A1*, its function or signaling, and hopefully, that can be investigated by future studies.

COL17A1 is one of the triple-helix collagen genes encoding collagen XVII, a type II transmembrane protein found in basal epithelial cells that can affect cell growth and migration (Natsuga et al., 2019; Kozawa et al., 2021). *COL17A1* also lacks relevant research in the field of IPF. Currently, research on *COL17A1* has focused on cancer and skin diseases (Nishie, 2020). Our study found that *COL17A1* overexpression was related to poor prognosis of SKCM and PAAD. Studies have shown that *COL17A1* is over-expressed in a variety of cancers (Thangavelu et al., 2016; Huang et al., 2022). In contrast, another study found that upregulation of *COL17A1* expression was related to better prognosis in breast cancer (Yodsurang et al., 2017). *COL17A1* inhibits cancer cell migration and invasion by inactivating AKT/mTOR pathway, and its over-expression is linked with longer survival in patients with invasive breast cancer (Lothong et al., 2021).

ITGA10 is a type II collagen-binding integrin first isolated from chondrocytes (Camper et al., 1998). *ITGA10* has the highest content in cartilage tissue and plays a crucial part in the formation of growth plates during bone development (Bengtsson et al., 2005). From the current overall research situation, the research on *ITGA10* mainly focuses on cancer. Our study suggested that increased *ITGA10* expression was linked with poor prognosis of SARC and longer survival of BRCA and SKCM. Previous studies have reported that *ITGA10* promotes drug resistance and proliferation of osteosarcoma cells by the activation of PI3K/AKT signaling pathway (Li et al., 2021). Similarly, *ITGA10* promotes myxofibrosarcoma survival and metastasis by activating TRIO/RAC and RICTOR signaling pathways, and antitumor effects were observed in mouse xenografts after *ITGA10* inhibition (Okada et al., 2016). In addition, dysregulation and carcinogenic effects of *ITGA10* had been observed in lung cancer, prostate cancer, and thyroid cancer (Mertens-Walker et al., 2015; Su et al., 2015; Saftencu et al., 2019). These findings suggest that *ITGA10* acts as an oncogene. According to our knowledge, *ITGA10* has not been reported on IPF, and more attention should be paid to IPF.

Different from *COL14A1*, *COL17A1* and *ITGA10*, *MMP7* had been supported by numerous literatures in the research field of IPF. *MMP7* is the smallest member of the matrix metalloproteinase family. *MMP7* plays a crucial part in the pathogenesis of fibrosis by degrading extracellular matrix proteins and activating multiple signaling molecules (Niu et al., 2019; Mahalanobish et al., 2020). *MMP7* is a target gene of Wnt/ β -catenin and highly expressed in proliferative epithelial cells of IPF (Zuo et al., 2002; Fujishima et al., 2010). Previous studies have identified *MMP7* as a potential biomarker for IPF. For instance, *MMP-7* was identified as a predictor of survival in a combined model incorporating clinical parameters and *MUC5B* genotype (Peljto et al., 2013; Biondini et al., 2021). Consistent with previous studies, we found increased *MMP7* expression in IPF and negatively correlated with decreased FVC (Bauer et al., 2017). Some studies have shown that *MMP7* combined with other biomarkers may improve the survival prediction of IPF patients (Song et al., 2013; Hamai et al., 2016). In addition, a phase II clinical study showed that *MMP7* protein levels decreased in a dose-dependent manner after using JNK inhibitors, indicating that the use of *MMP7* to track IPF progression has potential clinical benefits (van der Velden et al., 2016). However, a recent study found that there was no difference in the baseline concentration of *MMP7* between IPF patients with or without disease progression, and short-term changes in its concentration could not reflect disease progression (Raghu et al., 2018; Khan et al., 2022). Another study indicated that *MMP7* was over-expressed in patients with subclinical interstitial lung disease and under-expressed in patients with mature IPF compared to healthy controls (Drakopanagiotakis et al., 2018). It is suggested that *MMP7* can be used as a potential marker for early detection of IPF. Besides, more and more evidences support *MMP7* as an oncogene involved in tumor cell proliferation, migration and apoptosis (Sun et al., 2021; Van Doren, 2022). *MMP7* is highly expressed in many cancers, and its expression is related to survival time and tumor stage (Lee et al., 2006; Liao et al., 2021). Knockdown of *MMP7* gene can inhibit tumor proliferation, migration and reduce drug resistance (Sanli et al., 2013; Yuan et al., 2020). Therefore, *MMP7* is expected to become a potential biomarker for evaluating tumor prognosis and a new target for tumor therapy.

GO enrichment analysis showed that BMDEGs were involved in the composition of basement membrane, extracellular matrix and endoplasmic reticulum cavity, and were related to extracellular matrix tissue, collagen metabolism and metalloproteinase activity. Alveolar epithelial damage and abnormal tissue repair are considered to be key factors in the development of IPF, which ultimately leads to the recruitment and activation of myofibroblasts to produce collagen-rich extracellular matrix. The deposition of extracellular matrix in IPF mainly involves matrix metalloproteinases (MMPs) and tissue inhibitors of metalloproteinases (TIMPs). More and more studies support the key role of MMPs in the pathogenesis of pulmonary fibrosis. Interestingly, some MMPs have pro-fibrotic effects, while others seem to play a protective role. In our study, we found that *MMP7* was over-expressed in IPF patients, and previous studies have shown that it contributes to the progression and adverse consequences of IPF, while *MMP19* seems to have a protective effect (Jara et al., 2015). Changes in the extracellular matrix of IPF can also affect the transcription of lung fibroblasts, resulting in abnormal translation of ECM proteins (Zolak and de Andrade, 2012). In addition, the degradation product of ECM (matrikines) also acts as a signal molecule and plays a central role in the fibrosis of IPF. Existing evidence suggests that ECM plays an important role in driving the circulation of pathogenic disease signals mediated by integrins, growth factors, matrikines, and MMPs (Hewlett et al., 2018). It is worth noting that the increased stiffness of ECM tissue is also a key driver of the fibrosis process. Compared with healthy lung scaffolds, collagen, proteoglycan and ECM glycoprotein in IPF scaffolds increased, but specific BMs proteins (such as laminin and collagen IV) decreased (Elowsson Rendin et al., 2019). New treatments for these ECM-driven processes are expected to bring benefits to IPF patients. Moreover, KEGG enrichment analysis showed that BMDEGs were related to Notch signaling pathway. It is reported that Notch signaling pathway plays a key role in the development, balance and regeneration of the respiratory system (Kiyokawa and Morimoto, 2020). The disorder of Notch signaling pathway is related to the occurrence of IPF, and the activation of Notch signaling can accelerate pulmonary fibrosis (Yang et al., 2022). Therefore, regulating the activation of Notch signaling pathway may be a new anti-fibrosis treatment strategy.

Although the pathogenesis of IPF remains unclear, a growing number of studies have implicated immune activation in its pathogenesis. Therefore, we used ssGSEA to further dissect the immune infiltration of the disease. In our results, we found that the expression of IHGs was correlated with different degrees of immune cell infiltration. The role of neutrophils in IPF remains unclear. On the one hand, inhibition of neutrophil chemokine *CXCL8* or lack of neutrophil elastase can reduce bleomycin-induced pulmonary fibrosis (Gregory et al., 2015; Gschwandtner et al., 2017). Similarly, increased neutrophils are associated with decreased FVC and all-cause mortality in IPF patients (Achaiah et al., 2022). It has been reported that deletion of exon 18 of *COL17A1* in mice leads to IL-17-related inflammatory responses in the skin and infiltration of eosinophils, neutrophils, T-cell and mast cells (Lindgren et al., 2023). XIV collagen is a neutrophil chemotactic factor that plays a role in neutrophil recruitment in rat inflammation (Nakagawa et al., 1999). On the other hand, the increase of neutrophils in BALF was not significantly related to the survival rate of IPF

patients (Tabuena et al., 2005). Fibrosis caused mice infected with bacteria to show a higher mortality rate through the destruction of neutrophils (Warheit-Niemi et al., 2022). However, whether neutrophils have prognostic value in IPF is unclear, and further studies are needed to confirm the role of neutrophils in IPF. B-cell were increased in patients with IPF, which is consistent with our current findings. Activation of immune responses and increased infiltration of B-cell and macrophages are associated with IPF development (Xu et al., 2021). Previous studies have shown that B-cell and BLyS are elevated in patients with IPF and are inversely associated with patient outcome (Heukels et al., 2019). Consistent with increased B-cell activation, plasma IgA was elevated in IPF patients and inversely correlated with FVC (Heukels et al., 2019). These findings suggest that inhibition of B-cell activation has potential therapeutic value for IPF. In addition, our study showed a decrease in Tregs in IPF patients, which is consistent with previous findings. There is conflicting evidence supporting the role of Tregs in IPF. Tregs were originally thought to have anti-fibrotic effects. Tregs in peripheral blood and BALF were significantly reduced in IPF patients and were associated with decreased FVC (Kotsianidis et al., 2009). Subsequent studies have shown that tregs can promote fibrosis. The decrease of Tregs in peripheral blood and BALF of IPF patients is related to the degree of fibrosis (Peng et al., 2014). In the bleomycin-induced PF model, depletion of Tregs resulted in reduction of fibrosis, while induction or metastasis of Tregs resulted in worsening of fibrosis (Birjandi et al., 2016). Tregs may play different roles in different stages of fibrosis. Tregs play a pro-fibrotic role in the early stage of PF and a protective role in the late stage (Boveda-Ruiz et al., 2013). Tregs can promote collagen deposition and release of TGF- β in the early stage of PF (Lo Re et al., 2011). Tregs depletion attenuates PF by promoting Th17 response and regulating the shift of disturbed Th1/Th2 balance to Th1 dominance in lung tissue (Xiong et al., 2015). Consequently, we speculate that Tregs regulate different T-cell subsets at different stages of pulmonary fibrosis, which may explain the different roles of Tregs in pulmonary fibrosis. Existing studies have shown that inhibition of macrophage migration inhibitory factor (MIF) can downregulate the expression level of *ITGA10* and reduce bleomycin-induced pulmonary inflammation and fibrosis in rats (Luo et al., 2021). The relationship between *ITGA10* and MIF is still lacking relevant evidence and the future development of inhibitors targeting MIF may contribute to the treatment of pulmonary fibrosis. It has been reported that activated *MMP7* is located on alveolar macrophages and proliferative epithelial cells (Fujishima et al., 2010). Future studies are needed to further confirm how IHGs participate in the pathological process of IPF by affecting immunity.

We further explored the correlation between IHGs expression and TME, immune subtypes and immune cell infiltration. Our study found that IHGs expression was linked with different levels of immune and stromal cell infiltration. Further analysis revealed that *COL14A1* was positively correlated with CAF, DCs, Endo, HSC, Macrophage, Monocyte and Tregs. *ITGA10* was positively correlated with CAF, Endo, HSC, Neutrophil and Tregs. *MMP7* was positively correlated with CAF, DCs, Macrophage and Monocyte. The correlation between *COL17A1* and immune cells was not prominent. In addition, we also found that *COL14A1*, *COL17A1*, and *MMP7* were associated with more invasive immune subtypes, including C1, C2, and C6 subtypes. These results suggest that changes in immune and stromal cell composition

make IHGs have different clinical features and immunotherapy responses. The relationship between IHGs expression and TME needs to be further studied at cellular and molecular levels.

We also explored the relationship between IHGs expression and immune checkpoint, tumor stemness score, TMB, and MSI. The results showed that IHGs expression was significantly related to RNAss and DNAss in most tumors. Previous studies have reported that higher stemness scores are linked with stronger tumor stem cell dedifferentiation and active biological processes, suggesting potential targets for chemotherapy drug development in cancer patients (Malta et al., 2018). IHGs expression level and immune checkpoint analysis showed that there was significant correlation between IHGs expression level and immune checkpoint in different tumors. Previous studies have shown that TMB is a good biomarker for predicting immunotherapy response in tumor patients (Goodman et al., 2017; Chan et al., 2019). MSI is also associated with prognosis, and high MSI indicates better prognosis (Ganesh et al., 2019). Our study suggested that IHGs expression was significantly related to TMB and MSI. These results reveal that immunotherapy may have potential benefits for cancer patients and may also help clinicians quickly identify patients who respond to immunotherapy. However, more studies at the molecular level are needed to fully explain the relationship between IHGs and immune response.

However, our research also has some shortcomings. Firstly, the biological mechanisms of *COL14A1*, *COL17A1*, *ITGA10* and *MMP7* in IPF and cancer are still unclear. Second, the results of this study need to be confirmed by relevant animals and human experiments. In the future research, we will continue to pay attention to the role of *COL14A1*, *COL17A1*, *ITGA10* and *MMP7* in IPF.

5 Conclusion

In summary, our study shows that BMs and immune disorders are closely associated with IPF. The IPF risk model based on IHGs showed that the high expression of *COL14A1*, *COL17A1*, *ITGA10* and *MMP7* was positively related to the risk of IPF. It was further confirmed that the AUC of the training set was 0.941 and that of the verification set was 0.917, indicating that *COL14A1*, *COL17A1*, *ITGA10* and *MMP7* were potential biomarkers for predicting the risk of IPF. Pan-cancer analysis showed that IHGs were related to prognosis, immune infiltration and drug sensitivity of cancer patients, and were expected to become new biomarkers for cancer patients. However, multicenter, large-scale and prospective studies are needed to confirm our results before *COL14A1*, *COL17A1*, *ITGA10* and *MMP7* are applied clinically.

Objective: We explore the candidate susceptibility genes for influenza A virus (IAV), measles, rubella, and mumps and their underlying biological mechanisms.

Methods: We downloaded the genome-wide association study summary data of four virus-specific immunoglobulin G (IgG) level data sets (anti-IAV IgG, anti-measles IgG, anti-rubella IgG, and anti-mumps virus IgG levels) and integrated them with reference models of three potential tissues from the Genotype-Tissue Expression (GTEx) project, namely, whole blood, lung, and transformed fibroblast cells, to identify genes whose expression is predicted to be associated with IAV, measles, mumps, and rubella.

Results: We identified 19 significant genes (ULK4, AC010132.11, SURF1, NIPAL2, TRAP1, TAF1C, AC000078.5, RP4-639F20.1, RMDN2, ATP1B3, SRSF12, RP11-477D19.2, TFB1M, XXyac-YX65C7_A.2, TAF1C, PCGF2, and BNIP1) associated with IAV at a Bonferroni-corrected threshold of $p < 0.05$; 14 significant genes (SOAT1, COLGALT2, AC021860.1, HCG11, METTL21B, MRPL10, GSTM4, PAQR6, RP11-617D20.1, SNX8, METTL21B, ANKRD27, CBWD2, and TSFM) associated with measles at a Bonferroni-corrected threshold of $p < 0.05$; 15 significant genes (MTOR, LAMC1, TRIM38, U91328.21, POLR2J, SCRN2, Smpd4, UBN1, CNTROB, SCRN2, HOXB-AS1, SLC14A1, AC007566.10, AC093668.2, and CPD) associated with mumps at a Bonferroni-corrected threshold of $p < 0.05$; and 13 significant genes (JAGN1, RRP12, RP11-452K12.7, CASP7, AP3S2, IL17RC, FAM86HP, AMACR, RRP12, PPP2R1B, C11orf1, DLAT, and TMEM117) associated with rubella at a Bonferroni-corrected threshold of $p < 0.05$.

Conclusions: We have identified several candidate genes for IAV, measles, mumps, and rubella in multiple tissues. Our research may further our understanding of the pathogenesis of infectious respiratory diseases.

Introduction

Although respiratory infections are largely preventable causes of illness and death, they remain the leading cause of death from infectious diseases worldwide, ranking fifth among all total causes of death (GBD 2015 LRI Collaborators, 2017). Influenza A virus (IAV), measles virus, rubella virus, and mumps virus infect a wide range of hosts, are highly transmissible and are prone to a mutation that can cause pandemics in a short period of time, placing an enormous burden and pressure on public health systems (Marshall and Plotkin, 2019; Harrington et al., 2021; Iacobucci, 2022; Raghunathan and Orenstein, 2022). The incidence of IAV, measles, mumps, and rubella has decreased drastically following the implementation of vaccination programs. However, the segmented genome of IAV allows for easy recombination and antigenic shift, resulting in novel antigens (Bouvier and Palese, 2008). Thus, the ability of IAV to rapidly evolve can result in highly pathogenic viral strains. Measles and rubella remain endemic in many countries, leading to the importation of cases and occasional local transmission within China, and the resurgence of mumps has recently been reported, with outbreaks still occurring and challenges remaining while controlling these diseases (Kauffmann et al., 2021). There is considerable variation in the severity of respiratory infections caused by viral infections. There are major determinants of this variability, such as intrinsic virus pathogenicity, acquired host factors (e.g., immunity and coexisting conditions), and innate host susceptibility. While viral genetic determinants of respiratory disease severity and host immunity have been well studied, host genetic determinants have been much less explored (Kennedy et al., 2014; Voigt et al., 2018; Sabikunnahar et al., 2022).

Genome-wide association studies (GWAS) are effective methods for understanding the genetic basis of many complex traits in common human diseases (Hayes, 2013). In particular, these have proven to be well-suited for identifying common single-nucleotide polymorphism (SNP) variants with moderate to large effects on phenotypes (Gorlova et al., 2022). However, the specific biological mechanisms and functional consequences of many of the genetic variants identified by the GWAS remain unclear, especially their role in disease severity; that is, GWAS methods may miss small effect-trait associations. Gene expression is an intermediate phenotype between genetic variation and an underlying disease predisposition trait (Albert and Kruglyak, 2015). Many genetic variants affect complex traits by regulating gene expressions. Unfortunately, large-scale expression-trait associations are hampered by sample availability and cost, as well as intrinsic factors and small effects. Therefore, to address these issues, transcriptome-wide association studies (TWASs) were developed, which integrate gene expression into large-scale GWAS (Derks and Gamazon, 2020). Through extensive simulation of existing GWAS data, TWASs have identified candidate genes associated with mental disorders (Thériault et al., 2018), calcified aortic stenosis (Liu et al., 2020), pancreatic cancer (Lin et al., 2017), and inflammatory biological age (Zhang et al., 2022). However, for many complex traits, biologically relevant tissues are unknown. Most existing studies identify gene-trait associations on the basis of a single tissue, whereby the significant gene effects that are identified get inflated. In addition, it has been shown that eQTLs with larger effects tend to regulate gene expressions in multiple tissues. The TWAS analysis of multiple tissues improves the accuracy of the results.

There have been some studies exploring the association of respiratory infectious diseases with some human tissues. Pulmonary inflammation and airway epithelial injury are hallmarks of human pulmonary infectious diseases. The association of HLA alleles with respiratory infectious diseases in lung cells has been confirmed by Zhang et al. (2022). Moreover, Xiao et al. (2023) found that interleukin-11 (IL-11) as a fibrotic factor may be associated with respiratory diseases leading to respiratory failure or even death. These potential connections deserve our attention.

In this study, we used TWASs to explore genes associated with IAV, measles, rubella, and mumps. Given that respiratory infectious diseases are associated with multiple tissues, we used eQTL reference panels for three tissues, namely, whole blood, lung, and transformed fibroblast cells, and pooled the GWAS data for IAV, measles, rubella, and mumps to identify tissue-specific susceptibility genes. This study lays the foundation for further understanding the pathogenesis of these four viruses.

Methods

GWAS data collection and processing

We collected four virus-specific immunoglobulin G (IgG) level data sets (anti-IAV IgG, anti-measles IgG, anti-rubella IgG, and anti-mumps virus IgG levels) from the NHGRI-EBI GWAS directory (<https://www.ebi.ac.uk/gwas/downloads/summary-statistics>). These data sets were originally obtained from 1,000 healthy individuals (MI), and their serum prevalence rates were 77.7%, 88.5%, 93.5%, and 91.2%, respectively, for these four viruses (Scepanovic et al., 2018). Considering that the main unit of anti-IAV IgG quantitative unit is S/CO (signal/cut-off ratio), the main unit of anti-measles and mumps virus IgG level is IA (index antibody), and the main unit of anti-rubella virus IgG is UI/mL. We also use SD as the change unit. Then, we screened the above data for single-nucleotide polymorphisms (SNPs) for further analysis. We retained the following SNPs: 1) autosomes (1–22), 2) minimum allele frequencies (MAF) greater than 0.001, and 3) more than 70% of observers having these specific SNPs (Yang and Zhou, 2020; Yang and Zhou, 2022). We also plotted Manhattan plots and q-q plots for the processed GWAS data sets for four traits to show the frequency and distribution of their genes (Figure 1; Supplementary Figure S1).

Transcriptome-wide association analysis

We used FUSION to perform relevant TWAS tissue analysis using GWAS summary data formatted after the processing of whole blood, lung, and transformed fibroblast cells (Gusev et al., 2016). Specifically, FUSION uses the pre-calculated gene expression weight to perform summary statistics with respiratory infectious diseases GWAS and calculates the association between each gene and respiratory infectious diseases. Association statistics are defined as TWAS z-scores and estimated as follows:

$$Z_{\text{TWAS}} = WZ / (W \sum_{s,s} W^t)^{1/2}.$$

Genes significantly associated with the risk of rubella in each tissue.

0.035), and ANKRD27 ($p_{\text{adjusted}} = 0.044$) to be significantly associated with measles. Other significant genes included CBWD2 ($p_{\text{adjusted}} = 0.029$) and TSFM ($p_{\text{adjusted}} = 0.041$) in transformed fibroblast cells.

Multi-tissue transcriptome-wide significant genes of mumps

We used FUSION to assess the relationship between predictive gene expression and mumps. After Bonferroni correction, we found that 15 genes in the three tissues were significantly associated with mumps (Figure 2C; Table 3). In mumps, we found six significant genes, namely, MTOR ($p_{\text{adjusted}} = 0.029$), LAMC1 ($p_{\text{adjusted}} = 0.021$), TRIM38 ($p_{\text{adjusted}} = 0.014$), U91328.21 ($p_{\text{adjusted}} = 0.014$), POLR2J ($p_{\text{adjusted}} = 0.018$), and SCR2 ($p_{\text{adjusted}} = 0.031$) in the whole blood; similarly, in the lung tissue, we found Smpd4 ($p_{\text{adjusted}} = 0.022$), UBN1 ($p_{\text{adjusted}} = 0.049$), CNTROB ($p_{\text{adjusted}} = 0.046$), SCR2 ($p_{\text{adjusted}} = 0.008$), HOXB-AS1 ($p_{\text{adjusted}} = 0.048$), and SLC14A1 ($p_{\text{adjusted}} = 0.027$) as mumps-related genes, while in the transformed fibroblast cells, we found AC007566.10 ($p_{\text{adjusted}} = 0.023$), AC093668.2 ($p_{\text{adjusted}} = 0.047$), and CPD ($p_{\text{adjusted}} = 0.005$) as significantly associated with mumps.

Multi-tissue transcriptome-wide significant genes of rubella

We used FUSION to assess the relationship between predictive gene expression and rubella. After Bonferroni correction, we found that 13 genes in the three tissues were significantly associated with rubella (Figure 2D; Table 4). In rubella, we found five significant genes, namely, JAGN1 ($p_{\text{adjusted}} = 0.036$), RRP12 ($p_{\text{adjusted}} = 0.017$), RP11-452K12.7 ($p_{\text{adjusted}} = 0.006$), CASP7 ($p_{\text{adjusted}} = 0.048$), and AP3S2 ($p_{\text{adjusted}} = 0.020$) in the whole blood, while in the lung tissue, we found IL17RC ($p_{\text{adjusted}} = 0.035$), FAM86HP ($p_{\text{adjusted}} = 0.034$), AMACR ($p_{\text{adjusted}} = 0.012$), and RRP12 ($p_{\text{adjusted}} = 0.006$) to be significantly associated with rubella. Similarly, in transformed fibroblast cells, we found PPP2R1B ($p_{\text{adjusted}} = 0.022$), C11orf1 ($p_{\text{adjusted}} = 0.029$), DLAT ($p_{\text{adjusted}} = 0.045$), and TMEM117 ($p_{\text{adjusted}} = 0.046$) as rubella-related genes.

Discussion

In this study, we used tissue-specific TWAS to explore the association of genetically predicted gene expression with IAV,

CHR, the chromosome on which the identified gene is located; MODEL, models used for imputation in FUSION; TWAS.P, *p*-values for TWAS analysis in each tissue; P-Bonferroni, *p*-values corrected by Bonferroni for TWAS analysis in each tissue.

measles, rubella, and mumps and identified 19, 14, 15, and 13 genes in three tissues as potential IAV-, measles-, mumps-, and rubella- related genes, respectively. In IAV, including three in whole blood (ULK4, AC010132.11, and SURF1), four in the

lung tissue (NIPAL2, TRAP1, TAF1C, and AC000078.5), nine in the transformed fibroblast cells (RP4-639F20.1, RMDN2, ATP1B3, SRSF12, RP11-477D19.2, TFB1M, XXyac-YX65C7_A.2, TAF1C, and PCGF2), and one expressed in three tissues

as significantly associated with IAV (BNIP1). In measles, including six in whole blood (SOAT1, COLGALT2, AC021860.1, HCG11, METTL21B, and MRPL10), six in the lung tissue (GSTM4, PAQR6, RP11-617D20.1, SNX8, METTL21B, and ANKRD27), and two in the transformed fibroblast cells (CBWD2, and TSFM). In mumps, including six in whole blood (MTOR, LAMC1, TRIM38, U91328.21, POLR2J, and SCR2), six in the lung tissue (Smpd4, UBN1, CNTROB, SCR2, HOXB-AS1, and SLC14A1), and three in the transformed fibroblast cells (AC007566.10, AC093668.2, and CPD). In rubella, including five in whole blood (JAGN1, RRP12, RP11-452K12.7, CASP7, and AP3S2), four in the lung tissue (IL17RC, FAM86HP, AMACR, and RRP12), and four in the transformed fibroblast cells (PPP2R1B, C11orf1, DLAT, and TMEM117). The above 59 genes have never been clearly reported to be associated with IAV, measles, mumps, and rubella.

TNF receptor-associated protein-1 (TRAP1), a member of the mitochondria-specific Hsp90 family, is located in the mitochondrial matrix, mitochondrial endomembrane, and the intermembrane space (Cechetto and Gupta, 2000; Pridgeon et al., 2007). However, among the few real TRAP1 clients described, two are subunits of the electron transport chain complex (ETC), a component of the complex II succinate dehydrogenase subunit A/B (SDHA/B) (Sanchez-Martin et al., 2020; Sanchez-Martin et al., 2021), and complex IV cytochromes c oxidase subunit 2 (COXII) (Xiang et al., 2016; Xiang et al., 2019). The II/SDH complex is a protein complex containing iron and sulfur groups whose function is to transfer electrons from succinate to the coenzyme Q10-ubiquinone (III complex) (Bezawork-Geleta et al., 2017). TRAP1 leaves the SDH in a partially unfolded state. Inhibition of TRAP1 can release active SDH and increase its activity (Agarwal et al., 2019; Hu et al., 2020). In addition, SDH activity (Masgras et al., 2017; Hu et al., 2020) and oxygen consumption (Masgras et al., 2017) were negatively correlated with TRAP1 expression, suggesting that TRAP1 promotes the Warburg effect (Guzzo et al., 2014). It should be noted that SDH also oxidizes succinic acid to fumarate, thus integrating the TCA cycle, suggesting a broad impact of TRAP1 on mitochondrial metabolism (Guzzo et al., 2014; Hsu et al., 2016). It can be assumed that the abnormal expression of the TRAP1 gene may contribute to the development of IAV by affecting mitochondrial metabolic processes.

GSTM4 belongs to the mu class of glutathione S-transferase (GST). Compared to other GSTMs (Comstock et al., 1993), GSTM4 exhibits greater consistency in amino acid sequence but has significant differences in physicochemical properties and tissue distribution. GSTM4 does not exhibit activity comparable to standard TPS substrates, and its specific substrate has not been identified. It is well known that the GST gene is highly polymorphic to adapt to the growing number of exotic compounds (Hayes and Strange, 2000). This polymorphism can alter individual susceptibility to the disease and response to therapeutic agents. For example, the T2517C polymorphism in GSTM4 has been shown to be associated with an increased risk of lung cancer (Liloglou et al., 2002). The mechanism underlying this association is not yet clear.

Currently, there are few reports of the relationship between the GSTM4 gene and the disease. Efforts may be needed to verify its role in infectious respiratory diseases.

In addition to the aforementioned genes, we have identified other candidate genes (SOAT1, HCG11, PAQR6, and AP3S2) in different tissues, of which AP3S2 has been reported to be associated with the development of type 2 diabetes (Kazakova et al., 2017). Other genes have also been implicated in cancer. For example, SOAT1 has been linked to the development of stomach cancer (Zhu et al., 2021), and pancreatic cancer (Oni et al., 2020); HCG11 may influence the development of nasopharyngeal carcinoma (Zheng et al., 2022); the PAQR6 gene has also been associated with several cancers (Yang et al., 2021). Although there is little research on these genes and respiratory infectious diseases, the potential links between these genes deserve further attention in future studies.

In summary, our results list some genes for respiratory infections that have not been studied before. Based on the previous knowledge of these genes, this means that they may be involved in host infection through transcriptional processes of susceptible genes and RNA degradation processes. This study is helpful to deepen the understanding of the pathogenesis of respiratory infectious diseases.

Data availability statement

Publicly available data sets were analyzed in this study. These data can be found here: <https://www.ebi.ac.uk/gwas/downloads/summary-statistics>.

Author contributions

XZ, YZ, and LJ contributed equally to the conception, design, and execution of the study, as well as to the analysis and interpretation of data. XZ, YZ, LJ, XY, YZ, JT, JL, SY, RY, and PH drafted, revised, and approved the manuscript. RY and PH are the corresponding authors who took responsibility for the final submission. All authors agree to be accountable for all aspects of the work, ensuring the accuracy and integrity of the content.

Funding

This study was sponsored by the National Natural Science Foundation of China (82173585 and 82273741), the Natural Science Foundation of Jiangsu Province (BK20190106), and the Priority Academic Program Development of Jiangsu Higher Education Institutions (PAPD).

Acknowledgments

This study is a joint effort of many investigators and staff members, and their contributions are gratefully acknowledged.

Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Background: Crohn's disease (CD), a chronic gastrointestinal inflammatory disease, is increasing in China. With a focus on Han Chinese families with CD, the aim of this study was to find genetic variations that increase CD susceptibility by genome sequencing, genetic association, expression, and functional research.

Materials and methods: We performed family-based genome sequencing (WGS) analysis on 24 patients with CD from 12 families and then filtered shared potential causal variants by incorporating association results from meta-analyses of CD GWAS and immunology genes and *in silico* variant effect prediction algorithms. Replication analyses were performed in an independent cohort including 381 patients with CD and 381 control subjects.

Results: There were 92 genetic variants significantly associated with CD in Chinese individuals. Among them, 61 candidate loci were validated in replication analyses. As a result, patients carrying a rare frameshift variant (c.1143_1144insG; p. Leu381_Leu382fs) in gene *SIRPB1* had significantly higher risk to develop CD ($p = 0.03$, OR 4.59, 95% CI 0.98–21.36, 81.82% vs. 49.53%). The frameshift variation induced tyrosine phosphorylation of Syk, Akt, and Jak2, elevated the expression of *SIRPB1* at the mRNA and protein levels, activated DAP12, and controlled the activation of NF- κ B in macrophages. Additionally, it promoted the synthesis of the pro-inflammatory cytokines IL-1, TNF-, and IL-6.

Conclusion: Our results suggest that the rare gain-of-function frameshift variant in *SIRPB1* is associated in Han Chinese patients with CD. The functional mechanism of *SIRPB1* and its downstream inflammatory pathways was preliminarily explored in CD.

Introduction

Inflammatory bowel disease (IBD), which includes Crohn's disease (CD) and ulcerative colitis, is a complex polygenic disorder brought on by the improper activation of effector immunologic pathways in those with a genetic predisposition. Genome-wide association studies (GWAS) that look for genetic factors influencing disease start and progression have found 240 IBD-associated loci, which have greatly improved our understanding of the biology underlying these conditions (Anderson et al., 2011; de Lange et al., 2017; de Lange et al., 2017; Franke et al., 2010; Liu et al., 2015). The success of the GWAS approach is supported by the link between neighboring common variations in human populations, but it also makes it challenging to determine with accuracy which variant is causative, the molecular consequences of that variant, and frequently even which gene is perturbed. The association of uncommon protein-altering mutations that are expected to impart a higher risk of disease may help to explain some of the missing heritability in IBD. Because they are linked with fewer neighboring variants, rare variants with greater impact sizes may be easier to understand mechanistically. It is still unknown, nevertheless, how much of the heritability of complex disorders can be attributed to uncommon variations. The promise to better comprehend the molecular and genetic architecture of an exemplary complex disease is thus provided by well-powered investigations of uncommon variations in IBD.

IBD is assumed to have a significant genetic link because the most significant risk factor for the condition at any age is a family history of IBD (Childers et al., 2014; Kuwahara et al., 2012). Patients with IBD who have a family history of the condition frequently present it at a younger age, are more likely to have extra-intestinal manifestations, develop perforating disease, and need longer follow-up than patients without a family history, showing significant an increased genetic susceptibility to the condition (Kuwahara et al., 2012). Therefore, family-based IBD cohort genomic analyses are helpful for understanding the genetic architecture of IBD. IBD susceptibility is influenced by a variety of genetic variables. Whole genome sequencing (WGS), in conjunction with recent significant technological advancements, has made it possible to identify uncommon and novel harmful variants in IBD, providing a deeper understanding of genetic differences within the human genome. Due to this, GWAS have been created to objectively identify genetic risk factors for complex polygenic disorders. According to our hypothesis, rare or novel variations, such as those in genes linked to the innate immune system, are more likely to play a role in the development of CD in patients with a family history of the disease. We used WGS to investigate particular genes or pathways implicated in this disease state. Our capacity to research uncommon variations and ascertain the disease's genetic origin has been transformed by WGS. To address this question, in this study, we identified and replicated a novel rare causative frameshift variant associated with CD and explored into how it affected functionality.

Materials and methods

Study subjects

The genome sequence of 24 Han Chinese patients with CD from 12 families were obtained (Table 1). Written informed consent was provided by the attending parents or legal guardians of the pediatric participants. This study was approved by the Research Ethics Committee (REC) of the Sixth Affiliated Hospital of Sun Yet Sen University (SYSU) (N0.2020ZSLYEC-006).

WGS

Using a QIAamp DNA Kit (QIAGEN, Hilden, Germany), genomic DNA was extracted from peripheral blood cells in accordance with the manufacturer's protocol. DNA samples were quantified using a Qubit (Thermo Fisher Scientific). A total of 2 µg of each DNA sample was sent to the Beijing Genome Institute (BGI, Shenzhen, China) for WGS using the BGISEQ-500, according to the manufacturer's guidelines. According to the manufacturer's recommendations, the genomic DNA was briefly split by ultrasound on a Covaris E220 (Covaris) to DNA segments between 50 bp–800 bp. The fragmented DNA was then exposed to end-repair, phosphorylation, and A-tailing procedures after being further chosen to 100bp–300bp using AMPure XP Beads (Beckman Coulter, Indiana, United States). The A-tailed segments were ligated to the BGISEQ-500 platform-specific adaptors, and the ligated fragments were then purified and amplified using PCR. Finally, single-stranded DNA circles were produced by the circularization process. The libraries were sequenced using 50 bp paired-end reads on the BGISEQ-500 platform following quantification and qualifying.

Genome sequence data analysis

SOAPnuke was used to filter the raw sequencing reads (Li et al., 2009b) (N rating >10%, low quality rating >50%, and quality rating <5) and Burrows-Wheeler Aligner (BWA v0.7.17) to align to the UCSC human reference genome (hg19) (Li and Durbin, 2009; Li and Durbin, 2010). The coordinates were sorted using Samtools (version 1.3.1) and duplicates were identified using Picard (version 1.129, <http://picard.sourceforge.net>) (Li et al., 2009a). Using GATK HaplotypeCaller (McKenna et al., 2010), single nucleotide substitution variants (SNV) and brief insertions and deletions (indels) were identified (McKenna et al., 2010). We used the GATK Variant Quality Score Recalibration (VQSR) that uses machine learning algorithm to filter the raw variant callset. The GATK VQSR used high-quality known variant sets as training and truth resources and built a predictive model to filter spurious variants. The SNPs and InDels marked PASS in the output VCF file were high-confidence variation set. For SNPs recalibration strategy, we used the following datasets and features to train the model. (a) Training sets: HapMap V3.3, Omni2.5 M genotyping array data and high-confidence SNP sites produced by the 1000 Genomes Project. (b) Features: Coverage (DP), Quality/depth (QD), Fisher

Prioritization of variants

All germline SNV and indels were annotated using an in-house annotation pipeline, as described previously (Neveling et al., 2013; de Voer et al., 2013; Vissers et al., 2010). High-confidence calls (i.e., ≥ 10 reads, ≥ 5 variant reads, and $\geq 20\%$

variant reads) were subsequently prioritized for variants that were non-synonymous and were absent in our in-house variant database (2,037 in-house analyzed exomes, mostly from European ancestry). Next, we removed all variants present with a MAF of >0.001 in dbSNPv138, the National Heart, Lung, and Blood Institute (NHLBI) Exome Sequencing Project database (ESP, 6503 exomes, <http://evs.gs.washington.edu/EVS/>), the Exome Aggregation Consortium (Lek et al., 2016) and Thousand Genome Project. Subsequently, family index patients shared non-synonymous variants that result in alterations in protein function, including protein truncation, splice site defects and missense mutations at highly conserved (phyloP ≥ 3.0) nucleotide positions, were included in our analyses. Alamut v. 2.0 software (Interactive Biosoftware) and integrated mutation prediction software (align GVDV, SIFT and PolyPhen-2) (Adzhubei et al., 2010; Kumar et al., 2009; Vissers et al., 2010) packages were used for analyses of the identified variants. The

prediction of splicing effects was evaluated based on five different algorithms (SpliceSiteFinder, MaxEntScan, NNSPLICE, GeneSplicer, Human Splicing Finder) through the bioinformatics tools of the Alamut v.2.0 software.

Identification and selection of variants of candidate genes

By using GWAS, we first targeted germline variations in genes at susceptibility loci known to be linked to IBD (Anderson et al., 2011; de Lange et al., 2017; Ellinghaus et al., 2016; Huang et al., 2017; Julia et al., 2014; Kenny et al., 2012; Liu et al., 2015; Parkes et al., 2007; Yamazaki et al., 2013; Yang et al., 2014). Genetic defects in innate immunity that impair intestinal bacterial sensing are linked to the development of IBD (Cananzi et al., 2021). Recent developments in molecular biology have uncovered crucial details about the genetic basis of numerous inflammatory diseases. Next to the identification of variants in known IBD GWAS genes, we searched for potential pathogenic variants in novel candidate genes using the remaining genome data of our CD family cohort. We concentrated on genes that fulfilled the following criteria while choosing these variants: (Supplementary Table S2): 1) genes with variations that caused protein truncation (such as putative frameshifts, nonsense variations, and variations at canonical splice sites), as well as non-synonymous variations with a PhyloP score of more than 3.0, were chosen; 2) the International Union of Immunological Societies Expert Committee on Primary Immunodeficiency's collection of primary immune deficiency (PID) genes (Picard et al., 2015); and 3) genes involved in pathways implicated in IBD pathogenesis, including innate immune system, immune system, and neutrophil degranulation pathway (Belinky et al., 2015; Kanegane, 2018).

Sanger sequencing

After PCR amplification, WGS-identified candidate variant of *SIRPB1* was verified using Sanger sequencing. The Primer3 software program was used to build PCR primers *in silico*. Standard PCR procedures were used on an Applied Biosystems Dual 96-Well GeneAmp PCR System 9700 (primer sequences available upon request). Using the software package Vector NTI, variant analyses were carried out (Invitrogen, Paisley, United Kingdom).

Variant validation in independent cohort

Candidate variant validation analysis was performed on 381 probands with IBD and 381 unrelated individuals recruited by the Sixth Affiliated Hospital of SYSU using MassARRAY (Derkach et al., 2013). All individuals recruited were protected by the REC of the Sixth Affiliated Hospital of SYSU (N0.2020ZSLYEC-006). The phenotypes of the controls were assessed, and no known gastrointestinal or immunological findings were reported. Fisher's exact testing was conducted, and statistical significance was set at $p < 0.05$ (Derkach et al., 2013).

Functional validation of the *SIRPB1* variant allele

Histology

Both historical standard hematoxylin and eosin histological sections from the patient who was found to have the *SIRPB1* p. Leu381 Leu382fs variation and IBD controls were assessed.

Expression analysis

On 4 μ m segments of formalin-fixed paraffin-embedded (FFPE) tissue samples containing terminal ileum tissue from the patient identified as harboring the *SIRPB1* p. Leu381 _Leu382fs variation and IBD controls, *SIRPB1* expression was analyzed by immunohistochemistry (IHC). Using a BenchMark XT automated tissue staining machine (Ventana Medical Systems, Tucson, AZ, United States), IHC staining was carried out in accordance with the manufacturer's verified protocols.

Gene expression data

All the microarray samples used in this study were systematically searched and downloaded from NCBI-GEO (Barrett et al., 2013) after the manual curation of the sample details. We obtained gene expression data of mucosal biopsies in CD patients and normal controls from following array data series: GSE75214, GSE36807 and GSE59071. The bioinformatics online tool GEO2R was used to analyze the mRNA expression of *SIRPB1*.

Plasmid transfection

To study the variant type *in vitro* to understand its functional implications in more detail, we established THP-1 cell lines that stably expressed wild-type *SIRPB1* (*SIRPB1*^{wt}) and mutant *SIRPB1* (*SIRPB1*^{11143iG}, c.1143_1144insG; p. Leu381_Leu382fs). Human *SIRPB1*^{wt} and *SIRPB1*^{11143iG} expression vectors (pEZ-M02/*SIRPB1*^{wt} and pEZ-M02/*SIRPB1*^{11143iG}, respectively) were established. According to the manufacturer's instructions, Lipofectamine 2000 (Invitrogen; Thermo Fisher Scientific, Waltham, MA, United States) was used to transfect THP-1 cells with 0.5 μ g of either pEZ-M02/*SIRPB1*^{wt} and pEZ-M02/*SIRPB1*^{11143iG}. Continuous neomycin treatment at 450 μ g/mL was used to select transfectants that could consistently express the inserted vector plasmid (Thermo Fisher Scientific). The limited dilution approach was used to clone neomycin-resistant cells, which were then kept alive in medium containing neomycin.

Differentiation of THP-1 cells to macrophages

By administering THP-1 monocytes 100 ng/mL phorbol 12-myristate 13-acetate (PMA; Sigma) for 48 h, the macrophage-like state was generated. Then, THP-1 macrophages were transfected with 0.5 μ g pEZ-M02/*SIRPB1*^{wt} and pEZ-M02/*SIRPB1*^{11143iG} plasmid for 4 h. After transfection, THP-1 macrophages were incubated in

FIGURE 1

Heritability of enrolled CD family. Two pairs of fraternal twins, three pairs of identical twins, four pairs father or mother and daughter or son, two pairs of elder sister or brother and younger brother, one pair of aunt and niece were included in family based WGS analysis.

complete medium for 48 h and stimulated with LPS (100 ng/mL). THP-1 cells were lysed in ice-cold lysis buffer for western blotting, and proteins were separated on 10% SDS page. The main antibodies against DAP12, p-Syk/Syk, p-Akt/Akt, p-Jak2/Jak2, and anti-GAPDH were then used to probe the membranes. According to the manufacturer's instructions, the culture medium was suspended for ELISA assays and TNF- α , IL-1, and IL-6 ELISA kits were used to detect the substances.

Statistical analyses

Prism version 8.0 software (GraphPad) was used to perform the statistical analysis. Both the Student's t-test and the Dunnett's test were used to determine the significance of differences. When more than two groups were compared, a one-way ANOVA was performed. The data are shown as mean \pm SE, and a significance level of 0.05 was used.

Results

Clinical characteristics of the enrolled patients with familial CD

Studies of twins and familial clustering of disease clearly indicate that IBD, especially CD, is a hereditary disorder (Halfvarson et al., 2003). Therefore, we hypothesized that family-based CD is more probable to have occurred as a result of uncommon or unique variations and may play a role in the disease's development. Thus, 24 patients with CD from 12 families in the case database of our IBD center were enrolled for WGS analysis. Table 1 provides a summary of the clinical traits of the individuals that were enrolled. Among them, there were two pairs of fraternal twins, three pairs of identical twins, four pairs of father or mother and daughter or son, two pairs of elder sister or brother and younger brother, and one pair of aunt and niece (Figure 1). All the patients were of Han origin, including

13 men (54.17%) and 11 women (45.83%). The median age of participants in this study was 22 years (range 14–45 years). Regarding disease location, 20 patients were diagnosed with ileocolonic inflammation (L3, 83.33%), one patient with colonic inflammation (L2, 4.17%), 3 patients with ileal inflammation (L1, 12.50%), and six patients had concomitant upper gastrointestinal disease (25.00%). Regarding disease behavior, nine patients were accompanied with non-stricturing non-penetrating lesions (B1, 37.50%), six patients had stricturing lesions (B2, 25.00%), and nine patients had penetrating lesions (B3, 37.50%). A total of 13 patients (54.17%) had pelvic disease and six patients (25.00%) had a history of abdominal surgery.

IBD susceptibility analysis of identified gene variant

To further understand the genetic basis of IBD, we used WGS to look for uncommon, possibly disease-causing coding variations in familial CD patients (Table 1). A substantial percentage of coding variants discovered across individuals in a family were prioritized for further exploration using a series of progressive variant filters. We identified on average 3,430,329 variants (range: 3,393,972–3,466,204) per genome. A prioritization scheme was applied to identify candidate variants as shown in table 2. After rigorous bioinformatics analysis steps (see Methods), there were 92 genetic variants significantly associated with CD in Chinese individuals including several known IBD related gene including *NOD2*, *ZPBP2*, *TNFSF15*, *LSPI*, *SDCCAG3*, *MUC19*. Then, we adopted the MassArray Analyzer system (Sequenom, Inc., San Diego, CA, United States) for genotyping those genetic variants. We designed primers for 89 variants in Sequenom official websites, while, there is suitable primer for the remaining 3 variants. However, those 89 primers were distributed in 5 panels, due to the limited budget, only the top 2 largest panels (a total of 61 variants were included, about 30 variants per panel) used for the subsequently assay. We finally generated a candidate variants list

TABLE 2 Prioritization scheme for genome data analysis of 24 CD patients.

Type of prioritization filter	Remaining variants (n)
All variants	82,327,899
Coding region and canonical splice site variants after quality filtering (total ≥ 10 reads, ≥ 5 variant reads and $\geq 20\%$ variant reads)	13,819
Non-synonymous variants, canonical splice site variants	9,833
Family index patients shared Variants that result in alterations in protein function (protein truncation, splice site defects and missense mutations at highly conserved (phyloP ≥ 3.0) nucleotide positions.	2,749
Not in in-house database and MAF ≤ 0.001 in dbSNPv138, ESP, ExAC and Thousand Genome Project	2,007
Variants in genes at susceptibility loci known to be linked to IBD, primary immune deficiencies gene and IBD-related pathway genes and novel candidate variants	132
Variants pass IGV check	92
Variants for validation in large cohort	61 (4 variants in GWAS genes, 22 variants in IBD related pathway genes and 35 novel variants)

including 61 variants for replication analyses with an independent cohort including 381 patients with CD and 381 control subjects (Table 3).

Gain-of-function frameshift variant *SIRPB1* p. Leu381_Leu382fs in a cohort of patients with CD and healthy controls

Notably, we identified the frameshift variant *SIRPB1* p. Leu381_Leu382fs in two index patients, F7-II-1 and F7-II-2, from Family 7 (Figure 2). Patient F7-II-1 was the elder sister of patient F7-II-2, whose age was 23 years with a disease duration of about 2 years, and patient F7-II-2 was the younger brother whose age was 21 years with a disease duration of approximately 1 year. Both manifested as ileocolonic inflammation (L3). The disease behavior of F7-II-1 was non-stricturing non-penetrating (B1), whereas the disease behavior of F7-II-2 was penetrating (B3). For replication analysis, the blood sample of 384 CD patients including 104 females and 280 males in our database were used for microarray analysis to verify the susceptibility gene mutation. The mean age of these patients was 27.0 ± 10.4 years-old. The 384 blood samples of control group were collected from healthy testing population including 170 female and 214 male and the mean age of these patients was 34.7 ± 9.1 years-old. The unique uncommon frameshift variant in *SIRPB1* was considerably enriched in CD patients compared to controls, according to genotyping analysis ($p = 0.03$, OR 4.59, 95% CI 0.98–21.36, 81.82% vs. 49.53%). (Table 3). The clinical characteristics of patients with CD identified to harbor the *SIRPB1* p. Leu381_Leu382fs variant are listed in Table 4.

IHC analysis of the *SIRPB1* p. Leu381_Leu382fs variant

A member of the family of signal-regulating proteins (SIRP) and of the immunoglobulin superfamily, SIRP β (also known as

CD172b) is encoded by *SIRPB1* (van den Berg et al., 2005). Previous research on *SIRPB1* mostly focused on its biochemical properties and functions and discovered that it stimulates DAP12 and Syk tyrosine phosphorylation, which then activates the mitogen-activated protein kinase (MAPK) pathway to increase phagocytosis in macrophages (Hayashi et al., 2004). However, the role of *SIRPB1* in IBD pathogenesis has not yet been reported. Therefore, we first assessed the expression levels of *SIRPB1* by analyzing publicly available data from patients with IBD and healthy individuals. According to the findings, patients with active CD (A-CD) had considerably higher levels of *SIRPB1* expression in their ileocolonic tissue than either healthy individuals or patients with CD that was in remission (R-CD) (Figures 3G–I), indicating that *SIRPB1* is possibly involved in the progression of CD. Next, we assessed the expression levels of SIRP β in the ileocolonic tissue of variant and wild-type patients with CD using IHC (Supplementary Table S3). Notably, patients with CD and the *SIRPB1* variant exhibited significantly higher levels of SIRP β than those with CD and wild-type *SIRPB1* (Figures 3A,D). Consistently, SIRP β -mediated transduction signal molecules, such as DAP12 and p-Syk, were also significantly upregulated in patients with CD and the variant compared with WT controls (Figures 3B,C,E,F). Our data suggest that the higher expression of SIRP β was caused by the frameshift variation of *SIRPB1*.

Functional characterization of the rare *SIRPB1* frameshift variant (c.1143_1144insG; p. Leu381_Leu382fs)

As documented above, the frameshift variant in *SIRPB1* led to higher expression of SIRP β ; however, the function of the rare *SIRPB1* frameshift variant still needs to be elucidated. The interaction of SIRP β with the activating adaptor protein DAP12, which carries an immunoreceptor tyrosine-based activation motif (ITAM) and transmits activating signals, depends on the presence of

SIRPB1 gene led to an alteration of the amino acid sequence located both on the transmembrane and the cytoplasm. Therefore, we hypothesized that the frameshift variant of *SIRPB1* could make functional contributions to the inflammation process.

To investigate the potential effects of the identified novel frameshift variant of *SIRPB1*, Plasmids carrying either *SIRPB1*^{wt} and *SIRPB1*^{11143iG} sequence were transfected into THP-1 cells that had been stimulated with PMA for 48 h. In line with a previous

FIGURE 4

Predicted amino-acid sequence from wild-type control and patients with frameshift SIRPB1 mutation.

FIGURE 5

SIRPB1 mutation promote inflammatory response of macrophages *in vitro*. (A) NF-κB transcriptional activity of THP-1 cells from different groups was detected by a luciferase reporter assay; (B,C,D) IL-1β, IL-6 and TNFα levels in culture medium of THP-1 cells from different groups; (E) Western Blotting of signal transduction molecules in THP-1 cells from different groups.

report, compared with THP-1 cells transfected with the empty vector (NC), THP-1 cells with *SIRPB1* overexpression (*SIRPB1^{wt}*) exhibited increased activation of DAP12 and NF-κB and elicited tyrosine phosphorylation of Syk, Akt, and Jak2, causing increased

IL-1β, TNF-α, and IL-6 release (Figures 5A,B,C,D,E). Furthermore, compared with *SIRPB1^{wt}* cells, THP-1 cells expressing variant *SIRPB1* (*SIRPB1^{11143iG}*) displayed higher SIRPB expression, enhanced activation of DAP12 and NF-κB, increased tyrosine

phosphorylation of Syk, AKT, and Jak2, and higher secretion of IL-1 β , TNF- α , and IL-6 (Figures 5A,B,C,D,E). Taken together, our results show that the frameshift variant of *SIRPB1* amplified the function of the wild-type *SIRPB1* gene.

Discussion

SIRPs are a class of cell surface signaling receptors that are produced differently in myeloid and neural cells. They each include three extracellular Ig-like domains (Adams et al., 1998; Kharitonov et al., 1997). Despite having very identical extracellular domains, SIRPs can be distinguished as activating (α) or inhibitory (β) isoforms using conventional patterns in their cytoplasmic or transmembrane regions (Kharitonov et al., 1997). SIRP α , which binds to its ligand CD47, was found to inhibit signaling pathways that are mediated by receptor tyrosine kinase, as its cytoplasmic domains contain immunoreceptor tyrosine-based inhibitory motifs (ITIMs), which recruit the phosphatase SH2-domain-containing proteins SHP-1 and SHP-2 *in vivo* (Barclay and Brown, 2006). Contrary to SIRP α , SIRP β lacks the sequence patterns necessary to attach SHP-1 and SHP-2 in its short six-amino acid cytoplasmic domain. The transmembrane domain of SIRP β , however, has a charged amino acid residue that can bind to DAP12, which possesses a single cytoplasmic ITAM, and activate cell-mediated cytotoxicity and cytokine release (Dietrich et al., 2000; Liu et al., 2005; McVicar et al., 1998).

In the present study, a rare frameshift variant (c.1143_1144insG; p. Leu381_Leu382fs) in the innate immunity gene *SIRPB1* was identified. Genotyping analysis revealed that the novel frameshift variant in *SIRPB1* was significantly enriched in patients compared to that in healthy controls. Based on publicly available gene expression data, our research showed that patients with CD in the active stage had considerably higher relative expression of SIRP β , indicating that SIRP β is involved in the progression of intestinal inflammation. In addition, the frameshift variant of *SIRPB1* leads to an alteration of the amino acid sequence located both in the transmembrane and cytoplasmic regions. Therefore, we tested the functional contribution of the frameshift variant of *SIRPB1*. Our data show that, compared with WT controls, THP-1 cells transfected with the variant *SIRPB1* sequence displayed higher expression of SIRP β and its adaptor protein DAP12, enhanced activation of subsequent signal transduction, and increased pro-inflammatory cytokines production and NF- κ B expression. Accordingly, IHC data of ileocolonic tissue implied that patients with CD and variant *SIRPB1* expressed higher levels of SIRP β and its adaptor protein DAP12. Collectively, we found a rare frameshift variant (c.1143_1144insG; p. Leu381_Leu382fs) in *SIRPB1* that leads to alterations in the amino acid sequence located both in the transmembrane and cytoplasmic domains, could contribute to inflammation exacerbation by promoting the expression of SIRP β and its adaptor protein, DAP12. We hypothesized that the frameshift variant in *SIRPB1* may result in conformational changes of SIRP β or form a functional cytoplasmic domain owing to a longer amino acid sequence, which needs to be elucidated in future studies.

In our study, the data analysis shows that the rare gain-of-function frameshift variant (c.1143_1144insG; p. Leu381_Leu382fs) in *SIRPB1* is associated with Han Chinese patients with CD and provides insights that the variant in *SIRPB1* upregulated the activation of NF- κ B and

increased the production of IL-1 β , TNF- α , and IL-6 by inducing DAP12, Syk, Akt, and Jak2 to become tyrosine phosphorylated in macrophages, CD pathogenesis is facilitated. This study has several limitations. The familiar CD patients and the subsequent cohort for replication analyses are all Han Chinese from a single IBD center, so, further validation in other population is necessary. As well, due to limited budget and lack of suitable primers, only 61 variants were validated in replication analyses. Although the function of frameshift variant in *SIRPB1* were explored *in vitro* using THP-1 cells, further investigation using other cell lines and also *in vivo* are required. And also, for replication analysis, a *p*-value <0.05 without multiple testing correction was used in validation, so, further function study was adopted to verify the susceptible possibility of the *SIRPB1* variant in CD patients.

Data availability statement

The data presented in the study are deposited in the SRA repository and can be accessed at: <https://dataview.ncbi.nlm.nih.gov/object/PRJNA962047>.

Ethics statement

The studies involving human participants were reviewed and approved by Research Ethics Committee (REC) of the Sixth Affiliated Hospital of Sun Yet Sen University. Written informed consent to participate in this study was provided by the participants' legal guardian/next of kin.

Psoriasis is an immune-mediated inflammatory skin disease typically characterized by erythematous and scaly plaques. It affects 3% of the Newfoundland population while only affecting 1.7% of the general Canadian population. Recent genome-wide association studies (GWAS) in psoriasis have identified more than 63 genetic susceptibility loci that individually have modest effects. Prior studies have shown that a genetic risk score (GRS) combining multiple loci can improve psoriasis disease prediction. However, these prior GRS studies have not fully explored the association of GRS with patient clinical characteristics. In this study, we calculated three types of GRS: one using all known GWAS SNPs (GRS-ALL), one using a subset of SNPs from the HLA region (GRS-HLA), and the last using non-HLA SNPs (GRS-noHLA). We examined the relationship between these GRS and a number of psoriasis features within a well characterized Newfoundland psoriasis cohort. We found that both GRS-ALL and GRS-HLA were significantly associated with early age of psoriasis onset, psoriasis severity, first presentation of psoriasis at the elbow or knee, and the total number of body locations affected, while only GRS-ALL was associated with a positive family history of psoriasis. GRS-noHLA was uniquely associated with genital psoriasis. These findings clarify the relationship of the HLA and non-HLA components of GRS with important clinical features of psoriasis.

KEYWORDS

genetic risk score (GRS), polygenic risk score (PRS), psoriasis, Newfoundland and Labrador, genetics, HLA

1 Introduction

Psoriasis is an immune-mediated chronic inflammatory disease characterized by erythematous and scaly skin plaques. It affects 3% of the Newfoundland population while only affecting 1.7% of the general Canadian population (Nall et al., 1999; Papp et al., 2011). The Newfoundland province of Canada is a genetically isolated population

comprising approximately 500,000 residents with 98% English or Irish descent (Rahman et al., 2003). Because Newfoundland rose from a limited founder population, it is an exceptional resource for studying familial disorders such as psoriasis which was found at a higher prevalence in Newfoundland compared to other white populations (Nall et al., 1999).

Although environmental triggers like stress, infection, and trauma can contribute to the development of psoriasis, family-based and population studies suggest an important genetic component to the development of psoriasis (Alshobaili et al., 2010; Chandran and Raychaudhuri, 2010; Capon, 2017). The pathogenesis of psoriasis involves the dysregulation of T cells, antigen presenting cells, and keratinocytes among many cell types. Genome-wide association studies (GWAS) in psoriasis have identified many susceptibility loci with modest individual effects (Cargill et al., 2007; Stuart et al., 2015; Tsoi et al., 2017). Among these, the *HLA-C*06:02* allele is thought to contribute the greatest genetic effect (Henseler and Christophers, 1985). A prior study showed that with each additional *HLA-C*06:02* risk allele (tagged by rs10484554), there was a 206% elevated risk of psoriasis (Chen et al., 2011). However, *HLA-C*06:02* only accounted for 6.7% of the genetic heritability found in psoriasis, suggesting the importance of other HLA genes and non-HLA genes in disease progression (Chen et al., 2011).

While psoriasis commonly presents on the scalp and extremities, it often first occurs on the extensor surfaces such as the elbows and knees. Psoriasis is classified into two types: Type 1 psoriasis (T1P) which starts before age 40, and T2P which starts at or after the age of 40 (Henseler and Christophers, 1985). T1P has been associated with a family history of psoriasis with involvement of *HLA-C*06:02* whereas T2P is less associated with a positive family history or involvement of *HLA-C*06:02*.

Prior studies have shown that combining many genetic susceptibility loci into an overall genetic risk score (GRS) can improve identification of people at risk for that disease (Weedon et al., 2006; Meigs et al., 2008; Abraham et al., 2021). Previous GRS studies in psoriasis have shown that GRS can be used for psoriasis disease prediction and shows an inverse correlation with age of onset (Chen et al., 2011; Lu et al., 2013; Tsoi et al., 2017). However, there is a lack of studies investigating the association of GRS with psoriasis clinical features.

In this study, we calculated three types of GRS: one using all known GWAS SNPs (GRS-ALL), one using a subset of SNPs from the HLA region (GRS-HLA), and the last using non-HLA SNPs (GRS-noHLA). In past GWAS studies of psoriasis, *HLA-C* has been identified as a highly associated locus. Our lab and others have uncovered many functional roles for HLA genes, so it is intuitive to set these SNPs apart as a functionally separate group of SNPs as they play a major role in antigen presentation (Chen et al., 2012; Zeng et al., 2013; Yanovsky et al., 2020; Ahn et al., 2021). The partitioning of non-HLA SNPs was performed to investigate their possible role independently from the HLA SNPs. We examined the relationship between these GRS and several psoriasis features within a Newfoundland cohort. These include family history, age of onset, psoriasis severity, locations ever affected by psoriasis, locations first affected by psoriasis, and total number of locations. In

addition, we explore how the association of GRS with these clinical features is modified by early-onset psoriasis *versus* late-onset psoriasis (T1P vs T2P).

2 Materials and methods

2.1 Cohort

The study cohort includes 654 psoriasis cases of European ancestry from the Newfoundland region of Canada. Psoriasis patients were residents of Newfoundland and Labrador that were clinically diagnosed with psoriasis by a dermatologist in the late 1980s and early 1990s. The cohort consisted of 52% female and 48% male patients with an average age of 41 with a standard deviation (SD) of 14. Clinical data collected included birthplace, maternal heritage, paternal heritage, race, BMI, gender, age of onset, relatives with psoriasis, body locations ever or first noted with psoriasis (hand, back of hand, palm, foot, sole, toe, nail, scalp, face, neck, arm, elbow, armpit, leg, knee, back, chest, trunk, genital area, other), other serious illnesses, psoriasis severity as rated by the dermatologist (i.e., mild, moderate, severe), and type of psoriasis (i.e., plaques, guttate, pustular, etc.). All data fields and category options are included in [Supplementary Table S1](#). All subjects provided written informed consent for use of their data and biosamples under IRB approval HREB #2019.188.

The independent validation cohort data were collected from 345 psoriasis patients of European descent at the University of California San Francisco (UCSF) Department of Dermatology enrolled between 2006 and 2016. The diagnosis of psoriasis was confirmed by a board-certified dermatologist, and study subjects completed a survey including demographic characteristics, medical history, and clinical features. The cohort consisted of 48% female and 52% male patients with an average age of 49 and a SD of 16. All subjects provided written informed consent for use of their data and biosamples under UCSF IRB# 10-02830.

DNA from both cohorts was genotyped on the Affymetrix United Kingdom Biobank Axiom Array (ThermoFisher) using a GeneTitan Multi-Channel Instrument (Applied Biosystems). SNPs were called using Analysis Power Tools 2.10.2.2 (Affymetrix, <https://www.affymetrix.com/support/developer/powertools/changelog/index.html>). Sample and SNPs passed quality control using the parameters of call rate >97% and Dish QC >82%. The resulting genotype vcf files were scanned with 'snppflip' (<https://github.com/biocore-ntnu/snppflip>) using the GRCh37 build of the human genome reference sequence maintained by the University of California, Santa Cruz (<http://hgdownload.cse.ucsc.edu/goldenPath/hg19/bigZips/hg19.fa.gz>) to identify reversed and ambiguous-stranded SNPs, which were flipped and removed (respectively) using Plink (<http://pngu.mgh.harvard.edu/purcell/plink/>) (Purcell et al., 2007), and the remaining sites were sorted using Plink (www.cog-genomics.org/plink/2.0/) (Chang et al., 2015). Clinical study data were managed using REDCap (Research Electronic Data Capture) hosted at University of California San Francisco (Harris et al., 2009; Harris et al., 2019). This web-based software provides an intuitive interface for validated data capture, audit trails for tracking data manipulation and exportation,

automated export procedures, and procedures for data integration with external sources.

2.2 SNP selection

We constructed our GRS using 88 SNPs and their corresponding odds ratios (ORs) from the largest published psoriasis GWAS meta-analysis identifying SNPs meeting genome-wide significance ($p < 5.0 \times 10^{-8}$) (Supplementary Table S2) (Tsoi et al., 2017). This meta-analysis included six GWAS, one exomechip, and one immunochip datasets of European ancestry. Many of the psoriasis loci from this study contained secondary independent signals. To ensure the effect sizes from the primary signals were not over- or underestimated, the ORs were calculated by conditioning on other independent signals within the same locus (Tsoi et al., 2017). This ensured the independent effect of each signal on psoriasis was properly represented despite any linkage disequilibrium (LD) structure. Moreover, because of the especially high LD with HLA loci, we calculated the pairwise linkage disequilibrium between the 11 HLA SNPs across a European population using the LDmatrix Tool within LDlink (Machiela and Chanock, 2015). This confirmed low LD between the 11 HLA SNPs selected, with 93% of the pairwise LD comparisons having an $R^2 < 0.1$.

2.3 Imputation

SNP data from the Affymetrix United Kingdom Biobank array were augmented with imputed SNPs from the Michigan Imputation Server (<https://imputationserver.sph.umich.edu>) (1000G Phase 3 v5 GRCh37 reference panel, rsqFilter off, Eagle v2.4 phasing, EUR population). SNP positions were translated to GRCh38 coordinates using the 'LiftoverVcf' command of Picard 2.23.3 (<http://broadinstitute.github.io/picard/>). The imputation quality of the 88 psoriasis SNPs was highly accurate with $R^2 > 0.8$ showing the high confidence and correct imputation of all SNPs (Supplementary Table S3). We utilized all 88 markers in our analysis as previous studies have indicated that utilizing imputation quality cutoffs has a detrimental impact on GRS discriminatory ability (Goldstein et al., 2015; Chen et al., 2020). Data is publicly available at <https://doi.org/10.6084/m9.figshare.21970847>.

2.4 GRS calculation

Initially, two approaches were used to calculate the GRS: the simple risk allele count (cGRS and the weighted method (GRS). Subsequent analyses found that the weighted GRS to be superior to cGRS, so only the weighted GRS results are presented. The weighted GRS was calculated as the sum of the number of risk alleles weighted by the OR of that allele. GRS calculation was performed on imputed continuous-valued dosages between 0 and 2 rather than number of risk alleles. The GRS-ALL was calculated as the weighted GRS using all 88 SNPs, the GRS-HLA was calculated using the 11 SNPs found in the HLA region (chr6:28510120-33480577 in GRCh38), and the GRS-noHLA was calculated using the 77 non-HLA SNPs. The calculations were performed in Plink.

FIGURE 1

Positive correlation between family score and GRS-ALL.

Coefficient = 0.022. $R^2 = 0.0067$, $p = 0.038$, $SE = 0.011$, $n = 495$. Family score calculated by summing the contributions from relatives affected by psoriasis as follows: first degree relative = 1, a second-degree relative = 0.5, a third-degree relative = 0.25.

2.5 Association testing

Association testing of GRS-ALL, GRS-HLA, and GRS-noHLA with psoriasis clinical features was performed using logistic regression or linear regression in R (v4.1.0). A p -value of less than 0.05 was deemed significant. The principal component analysis for genital psoriasis was performed in R (v4.1.0) using the `prcomp()` function in the `stats` (v4.1.0) package. The samples were grouped based on the presence of genital psoriasis. For each group, the top ten non-HLA SNPs in principal component 1 with the loadings of the greatest magnitude were further explored. Associations between the 88 loci and genital psoriasis were tested with SNPTEST v2.5.4 using the additive model ("frequentist 1") and genotype dosages imputed by MIS ("method expected") for all cohorts (Supplementary Table S4) (Wellcome Trust Case Control, 2007).

3 Results

3.1 Family history

The family score was calculated as the sum of all relatives diagnosed with psoriasis in which first-degree relatives were given a weight of 1, second-degree relatives were given a weight of 0.5, and third-degree relatives were given a weight of 0.25. A linear regression was used to evaluate the relationship between GRS and psoriasis family score. A significant positive association was found between GRS-ALL and the family score ($p = 0.038$; Figure 1) with and odds ratio (OR) [95% CI] of 1.02 [1.00-1.04]. Meanwhile, this

association was found to be nonsignificant when using GRS-HLA and GRS-noHLA. These results indicate that all SNPs regardless of loci cumulatively contribute to the family history.

3.2 Age of psoriasis onset

A linear regression analysis revealed a significant negative association between GRS-ALL and onset in which increasing GRS was associated with an earlier age of onset (coefficient = -0.341 , standard error (SE) = 0.09 , $R^2 = 0.023$, $p = 0.0001$, OR 0.71 [0.59 - 0.85]). The average age of onset was calculated for each GRS-ALL score quartile in which the first quartile had an average age of onset of 27.28 (SD = 13.76 , SE = 1.07) while the fourth quartile had an average of 20.63 (SD = 12.43 , SE = 0.97 ; Figure 2; Supplementary Table S5). The linear regression was repeated using GRS-HLA which yielded a more significant association (coefficient = -0.772 , SE = 0.156 , $R^2 = 0.0398$, $p = 1.03 \times 10^{-6}$, OR 0.46 [0.34 - 0.63]). Meanwhile, the results showed a similar trend but were nonsignificant when repeated with the GRS-noHLA. These results suggest that individuals with a higher GRS have an earlier age of onset and that this trend is driven by the HLA SNPs.

3.3 Psoriasis severity

An ordinal logistic regression was performed to evaluate the relationship between GRS and psoriasis severity level, categorized as mild, moderate, and severe, as rated by a dermatologist. The patients were categorized based on dermatologist diagnosis and discretion. There was a significant association between GRS-ALL

and severity (SE = 0.0152 , $p = 0.045$, OR 1.02 [1.00 - 1.06]) and between GRS-HLA and severity (SE = 0.027 , $p = 1.64 \times 10^{-3}$, OR 1.09 [1.03 - 1.15]; Figure 3A; Supplementary Table S6). Meanwhile, there was a non-significant association between GRS-noHLA and severity. To ensure these results were not driven by non-plaque forms of psoriasis (e.g., pustular, erythrodermic) being considered more severe, a sensitivity analysis was performed that included only plaque psoriasis ($n = 361$), which also confirmed the association of GRS-ALL and GRS-HLA with severity while there was no significant association with GRS-noHLA. These results suggest that the HLA SNPs are primarily responsible for psoriasis severity.

3.4 Locations ever affected by psoriasis

Linear regression revealed that GRS-ALL correlated positively with the total number of locations ever affected by psoriasis ($p = 1.25e-10$, SE = 0.023 , $n = 649$, OR 1.16 [1.11 - 1.21]; Supplementary Figure S1), with a stronger positive correlation observed between GRS-HLA and total locations ever affected (coefficient = 0.295 , $R^2 = 0.077$, $p = 3.37 \times 10^{-13}$, SE = 0.040 , $n = 649$, OR 1.34 [1.24 - 1.45]). Meanwhile, there was a nonsignificant weaker positive correlation when using GRS-noHLA.

A logistic regression was also performed to evaluate the effects of GRS on appearance of psoriasis at 30 different locations (Supplementary Table S7). GRS-ALL and GRS-HLA were both significantly associated with a number of individual body locations. With respect to the incidence of psoriasis at specific locations, only GRS-noHLA had a significant effect on the appearance of psoriasis in the genital area, which was not observed in GRS-ALL and GRS-HLA. These results indicate that patients with higher GRS have more total body locations ever noted with psoriasis, many of which are driven by HLA SNPs; however, the genital area was strongly associated with non-HLA SNPs.

Intrigued by this novel association of genital psoriasis with non-HLA SNPs, we examined this in an independent UCSF cohort of 345 European psoriasis patients of which 32% have genital psoriasis (110 genital, 235 non-genital). In this cohort, genital psoriasis was also found to be strongly associated with GRS-noHLA and GRS-ALL ($p < 0.05$) while it was not associated with GRS-HLA (Supplementary Table S7). This independent dataset provides additional evidence for the association between genital psoriasis and non-HLA SNPs.

To explore the biological basis for the association between non-HLA SNPs and genital psoriasis, an association test between the 88 loci and genital psoriasis was performed. Of these, five SNPs and four SNPs were found to be significant in the Newfoundland and UCSF cohort, respectively, but were found to be insignificant after false discovery rate (FDR) adjustment (Supplementary Table S4). A principal component analysis was also performed to identify which non-HLA SNPs contribute the greatest discriminatory power for genital versus non-genital psoriasis (Supplementary Figure S2). SNPs identified as contributing to genital psoriasis included those near *IFIH1* (rs3747517), *UBE2L3* (rs2256609), rs12651787, and rs100040411. SNPs identified as contributing to non-genital psoriasis included *IFIH1* (rs2111485), *ERAP1* (rs39841), *DDX58* (rs11795343), rs2057338, and rs8128234.

3.5 First location affected by psoriasis

A logistic regression revealed that a high GRS-ALL was significantly associated with the initial presentation of psoriasis at the elbow ($p = 0.005$) and knee ($p = 0.025$) but not with the initial presentation at the other 18 body locations (Supplementary Table S8). This association was more significant when using GRS-HLA ($p = 1.10 \times 10^{-5}$ and $p = 1.23 \times 10^{-3}$ for

elbow and knee, respectively). There were no significant effects of GRS-noHLA on the first location psoriasis presented.

As psoriasis often first presents on the elbow or knee location, patients were then grouped into a combined “Elbow or Knee” versus “Other” category of first presentation. Patients with “Elbow or Knee” first presentation had a significantly higher GRS-ALL and GRS-HLA compared to those who had psoriasis present at other locations first ($p =$

TABLE 1 Summary of Results (- if $p > 0.05$, + if $p < 0.05$, ++ if $p < 0.01$, +++ if $p < 0.001$, ++++ if $p < 0.0001$).

Elbow or Knee (n = 649)	All	+ (0.97, 0.94-0.99)	++++ (0.92, 0.88-0.96)	-(1.00, 0.97-1.03)
Genital Psoriasis (n = 649)	All	-(0.96, 0.93-0.99)	-(0.96, 0.91-1.00)	+ (0.97, 0.94-1.00)

0.018 and $p = 0.00011$ respectively; Figure 4). Meanwhile, there was no significant difference in GRS-noHLA between those that presented at the “Elbow or Knee” first and those that presented at other locations first. A logistic regression was also performed to evaluate the effect of GRS on the outcome “Elbow or Knee” or “Other”. GRS-ALL and GRS-HLA were significantly associated with presentation at the “Elbow or Knee” first ($p = 0.019$, OR 0.97 [0.94-0.99] and $p = 0.0001$, OR 0.92 [0.88-0.96] respectively) while GRS-noHLA was not (Table 1). Together, these results suggest that HLA SNPs are driving the first presentation of psoriasis at the elbow or knee.

3.6 Type 1 vs. type 2 psoriasis

The psoriasis subjects were split into an early-onset (age of onset <40) T1P and a late-onset (age of onset ≥ 40) T2P group, and T1P had significantly higher GRS than T2P when using GRS-ALL

and GRS-HLA ($p = 0.0025$ and $p = 0.00015$ respectively; Figure 5). A linear regression analysis was performed within each onset group. In T1P, there was a significant negative association between GRS-ALL (coefficient = -0.203 , $R^2 = 0.0206$, $p = 0.00084$, SE = 0.06, $n = 487$, OR 0.82 [0.59-0.85]). This was repeated with GRS-HLA which yielded a stronger and more significant association (coefficient = -0.367 , $R^2 = 0.0216$, $p = 0.00067$, SE = 0.11, $n = 487$, OR 0.69 [0.56-0.86]). When this was repeated with GRS-noHLA, the trend was weak and the association was nonsignificant (coefficient = -0.106 , $R^2 = 0.0048$, $p = 0.123$, SE = 0.07, $n = 487$, OR 0.90 [0.78-1.03]). In T2P, there was a nonsignificant negative association between GRS-ALL and GRS-HLA with onset; however, there was a significant positive correlation between GRS-noHLA and onset (coefficient = 0.434, $R^2 = 0.041$, $p = 0.039$, SE = 0.21, $n = 79$). These findings suggest an association between non-HLA SNPs and age of onset in the late-onset psoriasis group.

Within the T1P and T2P onset groups, the association between GRS and severity was also analyzed. An ordinal logistic regression

was performed, and the only significant association was found in T1P using GRS-HLA (SE = 0.031, $p = 0.049$, OR 1.09 [1.03–1.16]). When comparing the GRS-HLA between the severity levels with a Kruskal–Wallis test followed by a pairwise Wilcoxon rank sum test, there was a significantly higher GRS in the moderate compared to the mild group within T1P ($p = 0.001$, Figure 3B). There was no clear trend and a nonsignificant association in T1P using GRS-ALL and GRS-noHLA and in T2P using all three GRS.

The association between GRS and total number of psoriasis locations was also analyzed within the onset groups. A linear regression analysis revealed a significant association in T1P using GRS-ALL ($p = 1.40 \times 10^{-6}$, OR 1.13 [1.08–1.19]; Supplementary Figure S1A). This association was stronger and more significant using GRS-HLA (coefficient = 0.124, $R^2 = 0.045$, $p = 1.401 \times 10^{-6}$, SE = 0.025, $n = 487$, OR 1.34 [1.23–1.47]; Supplementary Figure S1B) while it was a nonsignificant positive association using GRS-noHLA (Supplementary Figure S1C). The trend was similar but nonsignificant in T2P for all three GRS. Overall, these results indicate that GRS is inversely related with age of onset in the T1P group while not significantly related to age of onset in the T2P group. The GRS was positively associated with psoriasis severity and total locations ever affected, specifically driven by the HLA SNPs within the early onset T1P group.

4 Discussion

In this study, we calculated the GRS-ALL, GRS-HLA, and GRS-noHLA and evaluated their correlation to psoriasis clinical features. Of note, among all psoriasis subjects, the mean GRS-ALL was 102.8, mean GRS-HLA was 12.1, and mean GRS-noHLA was 90.6. The fact that GRS-HLA is not the major quantitative contributor to GRS-ALL indicates that associations found significant for GRS-HLA but not for GRS-noHLA were not simply driven by statistical power.

Our data show that patients with a higher GRS-ALL had a higher family score; however, this association is nonsignificant when the GRS was split into GRS-HLA and GRS-noHLA suggesting that all SNPs regardless of loci cumulatively contribute to the family history. This is an interesting finding due to prior research indicating a strong association of family history with *HLA-C06:02* (Schmitt-Egenolf et al., 1993; Schmitt-Egenolf et al., 1996; Gudjonsson et al., 2002). We also found that patients with higher GRS-ALL had an earlier age of onset, and this association was found to be stronger and more significant with the GRS-HLA. This agrees with prior research showing that *HLA-C06:02* -positive patients show an earlier disease onset (Schmitt-Egenolf et al., 1993; Schmitt-Egenolf et al., 1996; Enerback et al., 1997; Gudjonsson et al., 2002). Our data also showed a significant association of GRS-ALL with psoriasis severity level, categorized as mild, moderate, and severe. This association was stronger when using GRS-HLA, suggesting that HLA SNPs could be driving the severity level. Prior studies showed an increasing severity in *HLA-Cw1*- and *HLA-Cw12*-positive patients (Onsun et al., 2019; Huang and Tsai, 2021). Interestingly, the moderate group showed a higher average GRS than the severe group which could be due to a variety of reasons. Besides random noise from sampling, this could in theory be due to specific rare psoriasis mutations, not captured by the common variants on SNP arrays, being responsible for the more severe cases of psoriasis.

We also explored the effects of GRS on the body locations ever affected and first affected by psoriasis. Our data showed that patients with a higher GRS-ALL had higher total locations affected by psoriasis. This association was more significant using GRS-HLA, suggesting that HLA SNPs could be driving this. GRS-HLA had a significant effect on the appearance of psoriasis on the hand, toe, nail, face, knee, back, chest, trunk which was unique to GRS-HLA. A prior study showed that *HLA-C*06:02*-positive patients had more extensive plaques on their arms, legs, and trunk (Gudjonsson et al., 2002). Interestingly, GRS-noHLA had a unique significant effect on the appearance of psoriasis in the genital area. While there has not yet been significant investigation into the pathology of genital or inverse psoriasis, it is known to display features atypical for plaque psoriasis (Knabel and Mudaliar, 2022). There has also been recent identification of rare gene variants in inverse psoriasis patients that have not previously been reported for psoriasis (Goblos et al., 2021).

In our follow-up analysis to explore the association between non-HLA SNPs and genital psoriasis, *IFIH1* (rs3747517) and *UBE2L3* (rs2256609) were found to contribute to genital psoriasis. Meanwhile, *IFIH1* (rs2111485) and *ERAP1* (rs39841) were found to contribute to non-genital psoriasis. Interestingly, a prior study showed that *IFIH1* is important for immune responses to *Candida* fungal infections (Jaeger et al., 2015). In addition, prior studies have associated *IFIH1* (rs3747517) and *UBE2L3* with an inability to clear hepatitis viruses, leading to chronic infection and increased inflammatory states (Liu et al., 2018; Zhu et al., 2019; Yao et al., 2021). *IFIH1* encodes a retinoic acid-inducible gene I (RIG-I)-like receptor that can sense viral RNA in order to establish a proper antiviral host response. *UBE2L3* is an E2 ubiquitin conjugating enzyme that aids in regulation of many signaling pathways including NF- κ B. *IFIH1* (rs2111485) and *ERAP1*, on the other hand, have previously been associated with spontaneous clearance of hepatitis virus and more efficient antigen processing during COVID-19 infection, respectively, allowing for faster resolution of inflammation (Jiang et al., 2019; D'Amico et al., 2021; Yao et al., 2021). *ERAP1* is a key component of MHC class I antigen processing and presentation. Given the diverse and abundant microbiota in the genital area, we hypothesize that inflammation mediated by innate anti-fungal or anti-viral mechanisms could be correlated with the development of genital psoriasis.

Our data also showed that GRS-ALL was significantly associated with the initial presentation of psoriasis at the elbow and knee. This association became more significant when using GRS-HLA, suggesting that HLA variants could be driving this initial presentation of psoriasis at the elbow and knee. It is commonly observed that psoriasis usually first affects the elbows and knees; however, to date, there have been no studies correlating this presentation with genetic susceptibility loci partitioned between the HLA and non-HLA regions as we have done here.

Our study included an in-depth analysis of the effect of GRS within psoriasis types (early-onset T1P vs late-onset T2P). We found that the T1P group had a significantly higher GRS-ALL and GRS-HLA compared to the T2P group. We also found that T1P patients with a higher GRS-ALL and GRS-HLA had an earlier age of onset. Meanwhile, this association was nonsignificant in the T2P patients. Our data also showed that the GRS-HLA was significantly associated with severity in the T1P patients. Additionally, a higher GRS-ALL and GRS-HLA were significantly associated with more locations ever afflicted by psoriasis in the T1P patients. These findings together suggest that the GRS, driven by HLA variants, affect a

number of clinical features in T1P patients and not in T2P patients. This agrees with previous studies showing that T1P is associated with *HLA-C*06:02* while other mutations are associated with T2P (Schmitt-Egenolf et al., 1993; Hebert et al., 2015; Kapiro et al., 2021). However, extensive research on the direct effects of HLA variants on T1P subphenotypes were not reported as done here.

It is important to note that this study focused on drawing direct correlations between clinical data and HLA SNPs and non-HLA SNPs. A separate study (manuscript in preparation) discusses the power of this GRS to distinguish phenotype association across multiple cohorts. Additionally, we chose to use the most robust SNPs from a prior meta-analysis to reduce noise from less informative SNPs; however, including additional SNPs could be useful for investigating more subtle genetic associations. Other GRS tools such as PRSice2 and PRS-CS can be utilized to optimize this SNP selection. While we have presented a hypothesis on why the non-HLA SNPs that had higher contribution to genital psoriasis, further studies are needed to understand what specific pathways could be driving this. With a larger dataset, additional partitions can be made to investigate the role of specific immune pathways.

In summary, we examined the relationship between GRS-ALL, GRS-HLA, and GRS-noHLA with multiple psoriasis clinical features within a Newfoundland cohort. We found that the GRS-ALL was significantly associated with positive family history while both GRS-ALL and GRS-HLA were significantly associated with early age of onset, severity, first presentation on elbow and knee, and total locations affected, especially in the early onset T1P patients. Our findings also reveal that non-HLA SNPs influence age of onset in late-onset psoriasis as well as the presence of genital psoriasis. While some of these trends support current knowledge regarding the role of HLA in psoriasis, to our knowledge, there have not yet been studies methodically looking at non-HLA SNPs with clinical data. Nor have there been studies looking at specific body locations and their association with HLA and non-HLA SNPs. Our findings advance our knowledge of how different psoriasis susceptibility variants influence the clinical expression of disease.

Data availability statement

The original contributions presented in the study are publicly available. This data can be found here: <https://doi.org/10.6084/m9.figshare.21970847>.

Ethics statement

The studies involving human participants were reviewed and approved by Newfoundland and Labrador Health Research Ethics

Board (HREB) #2019.188. Written informed consent to participate in this study was provided by the participants' legal guardian/next of kin.

Author contributions

AB performed the data analysis and wrote the manuscript with support from WL, SK, JL, FO, SK, and JL performed the computations. LT assisted with methods development. WL conceived the original idea and supervised the project. All authors contributed to the article and approved the submitted version.

Acknowledgments

We are grateful to all psoriasis patients that participated in this study. We thank the late Eugene Farber for his contribution to the Newfoundland cohort.

Conflict of interest

WL has received research grant funding from Abbvie, Amgen, Janssen, Leo, Novartis, Pfizer, Regeneron, and TRex Bio. LT has received support from Galderma, Janssen, and Novartis.

The remaining authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Publisher's note

Introduction: Asthma is a chronic disease of the airways that impairs normal breathing. The etiology of asthma is complex and involves multiple factors, including the environment and genetics, especially the distinct genetic architecture associated with ancestry. Compared to early-onset asthma, little is known about genetic predisposition to late-onset asthma. We investigated the race/ethnicity-specific relationship among genetic variants within the major histocompatibility complex (MHC) region and late-onset asthma in a North Carolina-based multiracial cohort of adults.

Methods: We stratified all analyses by self-reported race (i.e., White and Black) and adjusted all regression models for age, sex, and ancestry. We conducted association tests within the MHC region and performed fine-mapping analyses conditioned on the race/ethnicity-specific lead variant using whole-genome sequencing (WGS) data. We applied computational methods to infer human leukocyte antigen (HLA) alleles and residues at amino acid positions. We replicated findings in the UK Biobank.

Results: The lead signals, rs9265901 on the 5' end of HLA-B, rs55888430 on HLA-DOB, and rs117953947 on HCG17, were significantly associated with late-onset asthma in all, White, and Black participants, respectively (OR = 1.73, 95%CI: 1.31 to 2.14, $p = 3.62 \times 10^{-5}$; OR = 3.05, 95%CI: 1.86 to 4.98, $p = 8.85 \times 10^{-6}$; OR = 19.5, 95%CI: 4.37 to 87.2, $p = 9.97 \times 10^{-5}$, respectively). For the HLA analysis, HLA-B*40:02 and HLA-DRB1*04:05, HLA-B*40:02, HLA-C*04:01, and HLA-DRB1*04:05,

and HLA-DRB1*03:01 and HLA-DQB1 were significantly associated with late-onset asthma in all, White, and Black participants.

Conclusion: Multiple genetic variants within the MHC region were significantly associated with late-onset asthma, and the associations were significantly different by race/ethnicity group.

MHC, HLA allele, immune function, race, ethnicity, late-onset asthma

1 Introduction

Asthma is a chronic disease of the airways characterized by inflammation, mucus production, and reversible airway obstruction that impairs normal breathing. According to the Centers for Disease Control and American Thoracic Society, 21 million adults in the United States have asthma, and \$80 billion is spent annually on healthcare related to the disease (American Thoracic Society, 2018; Centers for Disease Control, 2022). The complex etiology of asthma involves multiple factors, including genetic and environmental risk factors.

Recent studies have revealed that asthma is not a single disease but rather comprises multiple phenotypes (Anderson, 2008; Lötvall et al., 2011). This phenotypic heterogeneity likely stems from the involvement of distinct biological mechanisms, a concept captured by the term “asthma endotypes.” An improved understanding of these endotypes may reveal novel pathways that can be selectively targeted for specific forms of asthma. Our understanding of early-onset, or childhood, asthma has improved, and genetic predisposition is known to play an important role. In general, individuals with early-onset asthma respond well to inhaled corticosteroids, which is the gold standard for asthma treatment (Hirano and Matsunaga, 2018). By contrast, individuals with late-onset asthma are often steroid-resistant, and the potential mechanisms that lead to late-onset asthma remain poorly understood (Hirano and Matsunaga, 2018). In particular, little is known about genetic predisposition to late-onset asthma. Improved knowledge of genes that affect late-onset asthma may reveal novel biological pathways for targeted therapies.

Genome-wide association studies (GWAS) are a fruitful approach to identifying genes associated with a wide array of diseases, including asthma. GWAS have consistently identified significant associations between various asthma phenotypes and genes within the major histocompatibility complex (MHC) and human leukocyte antigen (HLA) loci (Li et al., 2010; Galanter et al., 2014; Clay et al., 2022). The human MHC region, located on chromosome 6 with an approximate size of 150–180 Mb, is the most gene-dense area of the genome and harbors highly polymorphic genes, including HLA genes. The HLA system encodes a peptide-binding groove of the HLA molecule critical for antigen binding and T cell recognition and the subsequent activation of immune response upon antigen challenge and thus plays an essential role in adaptive immunity. However, the pathological roles of genes within the MHC region and HLA alleles in late-onset asthma remain unclear.

Prior GWAS have sometimes failed to replicate genetic associations in asthma, which has hampered efforts to delineate plausible mechanisms. This failure may be due to population

heterogeneity, diverse asthma phenotypes and endotypes, and limitations of single nucleotide polymorphism (SNP)-level studies. In addition, inference of accurate high-resolution HLA alleles and amino acid residues remains challenging due to the tight linkage disequilibrium (LD) across disease-associated MHC haplotypes and the highly polymorphic nature of associated variants. To address these issues and identify putative causal variants, we conducted race/ethnicity-stratified fine-mapping studies of the MHC region for late-onset asthma utilizing WGS samples collected from a North Carolina-based multiethnic adult cohort. We also applied appropriate and high-accuracy computational methods/tools to infer HLA alleles and amino acid positions and residues for individuals of African and European ancestry using WGS data. The results show heterogeneity at three levels of resolution, namely, single nucleotide variants (SNVs), HLA alleles, and amino acids.

2 Materials and methods

2.1 Study participants: PEGS cohort

The ongoing North Carolina-based Personalized Environment and Genes Study (PEGS) ($N = 19,672$) began recruiting participants in 2002 and collects questionnaire-based exposome and health history data. The race/ethnicity of PEGS participants is categorized into American Indian/Alaska Native, Asian, Black, Hispanic, Native Hawaiian/Pacific Islander, White, and other/multiple races/ethnicities. However, due to small sample sizes, we focused our analyses on three racial/ethnic groups: non-Hispanic Black individuals, non-Hispanic White individuals, and all individuals. PEGS is described in detail elsewhere (Lee et al., 2022). Local institutional review boards approved the studies, and all participants provided written informed consent.

2.2 Asthma case and control definition

For the late-onset asthma outcome, we assigned participants to the case group if they answered “YES” when asked if they have ever been diagnosed with asthma (as defined by Global Initiative for Asthma criteria) (Global Initiative for Asthma, 2022) by a physician, currently have asthma, do not have other respiratory diseases, including idiopathic pulmonary fibrosis (IPF), chronic obstructive pulmonary disease (COPD), and tuberculosis (TB), and were diagnosed with asthma at the age of 20 years or more. We assigned participants to the control group if they answered “NO”

when asked if they have ever been diagnosed with asthma, have other respiratory diseases, including IPF, COPD, and TB, and have a regular cough and/or breathlessness, regular wheezing, or whistling in the chest.

2.3 MHC region-wide allelic association tests

We performed race/ethnicity-stratified MHC region-wide association testing for late-onset asthma in 3,641 PEGS participants, adjusting for age, sex, and four ancestry groups. The results of the MHC region-wide association tests for each ancestry are described below and summarized in the [Supplementary Material](#).

2.4 Fine-mapping: conditional analysis

We built a multi-SNP logistic regression model, applying a forward selection procedure for all, White, and Black participants and adjusted for age, sex, and four ancestry groups, conditional on the lead SNP (Lee et al., 2020). Details of the fine-mapping conditional analysis can be found in the [Supplementary Material](#) (Supplementary Section S1.5; Supplementary Table S1).

2.5 Validation

To validate our results from the association tests, we examined associations of the lead SNPs for each analysis (all, White, and Black participants) in GWAS results from the Pan-UK Biobank (Pan-UK Biobank, 2022) for asthma and asthma-related phenotypes. The UK Biobank (RRID:SCR_012815) is a large-scale biomedical database with both genetic and phenotype data for several common diseases and traits for approximately 500,000 participants from the United Kingdom (Sudlow et al., 2015). The Pan-UK Biobank study conducted a multi-ancestry GWAS of 7,228 phenotypes, including asthma and asthma-related phenotypes such as allergic rhinitis, lung function, and respiratory infections. Summary statistics are available for each ancestry group and a meta-analysis across all populations.

2.6 Functional annotation of genetic variants

We conducted annotation for the lead SNP and candidate causal SNPs identified from the conditional analyses using publicly available data (Boyle et al., 2012; Carithers et al., 2015; Martin et al., 2017; Carvalho-Silva et al., 2019; Luo et al., 2020). The [Supplementary Material](#) provides more information (Supplementary Section S1.6).

2.7 Assembly of HLA alleles: Kourami

We used Kourami (RRID:SCR_022280), a graph-guided assembly technique, to generate four- and six-digit HLA

alleles for six common HLA genes types (HLA-A, -B, -C, -DQA, DQB, and -DRB) and 14 additional HLA genes (HLA-DOA, -DOB, -DMA, -DMB, -DPA1, -DPB1, -DRQ, -DRB3, -DRB5, -F, -G, -H, -J, and -L) (Lee and Kingsford, 2018). The [Supplementary Material](#) provides more information on Kourami (Supplementary Section S1.7).

2.8 Amino acid position inference

In addition to HLA alleles, we inferred residues at amino acid positions. We applied the CookHLA and HLA analysis toolkit (HATK) enrichment-free computational HLA imputation/inference methods (Choi et al., 2021; Cook et al., 2021). The [Supplementary Material](#) provides details (Supplementary Section S1.8).

2.9 Structure implications

We selected the highest-resolution X-ray crystal structures for HLA-DRB (pdb ID: 4x5w, resolution 1.34Å), HLA-B (pdb ID: 1K5N, resolution 1.09 Å), and HLA-C (pdb ID: 6JTO, resolution 1.70Å). Structures were rendered using Chimera (RRID:SCR_002959).

We conducted all statistical analyses in R Project for Statistical Computing (RRID:SCR_001905, version 4.2.1) and PLINK 2.0 (RRID:SCR_001757) (Purcell et al., 2007; Habu et al., 2014).

3 Results

3.1 Study participants

On average, asthma cases were older than controls (54.3 ± 11.1 and 50.3 ± 14.8 years, respectively: $p = 4.1 \times 10^{-4}$) (Supplementary Table S2). The proportion of males in the case group was lower than in the control group (15.5% vs. 32.8%: $p = 2.8 \times 10^{-6}$). The small differences in genomic ancestry proportions between cases and controls were not statistically significant except for Black participants ($18.5\% \pm 32.8\%$ and $12.6\% \pm 28.4\%$, respectively: $p = 7.3 \times 10^{-3}$). Figure 1 displays the variability of genomic ancestry proportions for individual participants, and Supplementary Figure S2 outlines the population structure of PEGS participants by self-reported race and ethnicity.

3.2 MHC region-wide association studies

We performed race/ethnicity-stratified MHC region-wide association testing for late-onset asthma in 3,641 PEGS participants, adjusting for covariates. We discovered two MHC region-wide peaks for all and White participants and a suggestive peak for Black participants after multiple testing correction (Figure 2). The most significant association for all participants is located near *HLA-B*. The lead signal, rs9265901, is on the 5' end of *HLA-B* (Figure 3). A one-unit increase in the affected allele (minor allele: G) was associated with 67% increased odds of being a case

FIGURE 1

Population structure of PEGS participants. We applied uniform manifold approximation and projection (UMAP) to visualize the genetic variability of study participants using the first 40 principal components of whole-genome sequencing data. Each circle represents a study participant, and the colors represent their self-reported race/ethnicity.

(OR = 1.73, 95%CI: 1.31 to 2.14, $p = 3.62 \times 10^{-5}$). For White participants, the lead SNP, rs55888430, is on *HLA-DOB* (OR = 3.05, 95%CI: 1.86 to 4.98, $p = 8.85 \times 10^{-6}$). For Black participants, the lead SNP, rs117953947, is on *HCG17* (OR = 19.5, 95%CI: 4.37 to 87.2, $p = 9.97 \times 10^{-5}$). The lead SNPs for each reference ancestry are weakly to moderately correlated with cis-eQTLs for multiple genes in multiple tissues according to the GTEx eQTL Browser (RRID:SCR_001618) (Table 1; Figure 4) (Carithers et al., 2015). The results of the MHC region-wide association tests for each ancestry are summarized in the Supplementary Material.

3.3 Fine-mapping: conditional analysis

To identify candidate causal variants, we conducted conditional analyses to determine associations between late-onset asthma and the affected/minor allele at an SNP. Because the different allelic association signals observed for different ancestries were not due to a single SNP, we further investigated the joint effects of multiple SNPs on late-onset asthma.

Using multi-SNP logistic regression models with a forward selection procedure, we identified 10, 9, and 12 significant, independent SNPs for all, White, and Black participants, respectively (Table 2). The effect estimates in Table 2

represent the association between an SNP and late-onset asthma, conditioned on the lead SNP and adjusted for covariates and additional SNPs. The table contains only SNPs that remained significant after adjusting for additional SNPs and covariates. Table 3 displays the associations and minor allele frequencies (MAF) of the lead SNPs across all strata. The Supplementary Material provides a full list of the selected SNPs (Supplementary Table S3).

After identifying candidate causal variants from the conditional analyses, we performed functional annotation of these SNPs to elucidate their potential biological roles in late-onset asthma in PEGS participants. Supplementary Table S4 is a full list of candidate causal variants. Based on annotation from publicly available data, three SNPs identified for all participants exhibit a regulatory function in white blood cells and lung tissue (Supplementary Table S5). rs4569, a 3'UTR variant of *LY6G5B*, was strongly correlated with the negative expression of *LY6G5C* in whole blood and lung tissue ($p = 1.3 \times 10^{-119}$ and $p = 1.8 \times 10^{-43}$, respectively) (Supplementary Table S4). A 5'UTR variant of *BRD2*, rs62407970, intersected with strong promoter-like signatures, including a DNase I hypersensitive site and a histone modification (H3K4me3 and H3K27ac ChIP-Seq) (cCRE accession ID: EH38E3701714). Multiple experimental data indicate that rs62407970 falls within the *POLR2A* transcription factor binding

site and may interact with *HLA-DPB2* in human lung fibroblast cells (IMR90) and mesenchymal stem cells (MES) (Boyle et al., 2012).

For White participants, the non-coding exon variant of *HCG24*, rs7754362, intersected with low DNase-seq and H3K27ac ChIP-Seq

peaks in lung tissue and CD14⁺ monocytes and high CTCF signals in human lung fibroblast cells (cCRE accession ID: EH38E3701814). In addition, ChIP-Seq experiments indicate that rs7754362 is located within a CTCF transcription factor binding site in blood and lung tissue. Long-range chromatic interaction data suggest that rs7754362 may interact with *HLA-DMA* and *BRD2* in IMR90 and MES cell lines. Within the genomic region identified for Black participants, the intron variant rs17198965 overlapped with strong promoter-like signatures, including high DNase-seq and H3K4me3 ChIP-Seq peaks. Experimental data suggest that rs17198965 resides in the binding site of transcription factor *EZH2* (cCRE accession ID: EH38E3700474).

3.4 Validation of lead SNPs

We examined the associations of the lead SNPs from our association analyses with asthma and asthma-related phenotypes in the UK Biobank data using Pan-UK Biobank GWAS results (Pan-UK Biobank, 2022). We found that the lead SNP for all participants, rs9265901, is associated with asthma ($OR = 1.04$, $p = 3.36 \times 10^{-4}$), atopic dermatitis ($OR = 1.12$, $p = 4.33 \times 10^{-5}$), decreased lung function ($\beta = -0.01$, $p = 1.47 \times 10^{-5}$), and allergic rhinitis ($OR = 1.04$, $p = 5.62 \times 10^{-6}$) in the UK Biobank (Raj et al., 2014). In addition, rs9265901 is associated with increased lymphocytes ($\beta = 0.06$, $p = 2.35 \times 10^{-135}$), eosinophils ($\beta = 0.03$, $p = 1.68 \times 10^{-25}$), and neutrophils ($\beta = 0.06$, $p = 1.33 \times 10^{-103}$) (Raj et al., 2014). The top SNP for White participants, rs55888430, is associated with increased odds of being an asthma case ($OR = 1.14$, $p = 1.78 \times 10^{-4}$), having upper respiratory infections ($OR = 1.30$, $p = 1.95 \times 10^{-3}$), and having increased eosinophils ($\beta = 0.05$, $p = 9.82 \times 10^{-16}$) (Poplin et al., 2018). However, the association of this variant with reduced odds of both late- and early-onset asthma has been reported elsewhere ($OR = 0.39$, $p = 3.2 \times 10^{-3}$; $OR = 0.41$, $p = 2.0 \times 10^{-4}$, respectively) (Poplin et al., 2018). Lastly, the lead variant for Black participants, rs117953647, is associated with opportunistic respiratory infection ($OR = 1.71$, $p = 1.82 \times 10^{-4}$), pneumonia ($OR = 2.55$, $p = 2.02 \times 10^{-3}$), and increased lymphocytes ($\beta = 0.03$, $p = 2.15 \times 10^{-4}$) (Manichaikul et al., 2010), further validating our findings and providing evidence supportive of the proposed ancestry-specific pathways.

3.5 HLA analysis: HLA alleles

For all participants, several classical HLA alleles were significantly associated with late-onset asthma after adjusting for covariates (Table 4). The strongest association was *HLA-B*40:02* ($OR = 3.18$, 95%CI: 1.63 to 6.18), which is concordant with the MHC-wide association test result indicating the lead SNP (rs9265901) is located near *HLA-B* (Supplementary Figure S3). The second strongest association was *HLA-DRB1*04:05* ($OR = 6.94$, 95%CI: 2.15 to 22.44). For White participants, two MHC class I alleles, *HLA-B*40:02* and *HLA-C*04:01*, and one MHC class II allele, *HLA-DRB1*04:05*, were significantly associated with late-onset asthma. *HLA-C*04:01* was protective for being a late-onset asthma case ($OR = 0.25$, 95%CI: 0.09 to 0.70) whereas *HLA-B*40:02* and *HLA-DRB1*04:05* increased the odds of being a case [($OR = 3.77$, 95%CI: 1.91 to 7.44; $OR = 8.19$, 95%CI: 2.51 to 26.79), respectively]. For Black participants, two MHC class II

alleles, *HLA-DRB1*03:01* and *HLA-DQB1*02:01*, were significantly associated with increased risk of being a late-onset asthma case [(OR = 4.00, 95%CI: 1.46 to 10.91; OR = 2.25, 95%CI: 1.09 to 4.65), respectively].

3.6 HLA analysis

In accordance with the HLA allele analysis results, within *HLA-DRB1*, the amino acid variants at positions 37 and 38 were significantly associated with late-onset asthma. Among the three allelic variants at position 38 (leucine, valine, alanine) and five variants at position 37 (serine, phenylalanine, tyrosine, asparagine, leucine), leucine was the strongest risk residue at both positions (Supplementary Figure S4E). Within *HLA-C*, threonine residue at position 73 and alanine residue at position 90 were associated with increased odds of being an asthma case (OR = 1.40, 95%CI: 1.13 to 1.74; OR = 1.44, 95%CI: 1.16 to 1.79, respectively). For White participants, the leucine allele at amino acid 103 within *HLA-B* was associated with reduced odds of being a late-onset asthma case (OR = 0.48, 95%CI: 0.30 to 0.74). For Black participants, threonine residue at position 73 within *HLA-C* was associated with a 126% increase in the odds of being an asthma case.

The crystal structures in Figure 5 demonstrate that *HLA-DRB1* residues at 37 and 38 are located on the peptide-binding surface. Residue 103 within *HLA-B*, which appears to interact with a peptide, may play an important role in maintaining the structural scaffold and creating a binding surface. Within *HLA-C*, residues 73 and 90 are located on the peptide-binding groove.

4 Discussion

4.1 Findings

Previous epidemiological studies and GWAS have identified potential biological mechanisms underlying asthma, but few studies have focused on late-onset asthma. Prior GWAS have identified variants within the MHC region that are significantly associated with various asthma phenotypes (Li et al., 2010; Galanter et al., 2014). The MHC locus is the most gene-diverse and gene-dense region of the human genome, and the genetic architecture of the region is shaped by multiple factors, including gene shuffling and selective pressure in response to migration-related exposure to various environmental pathogens (Prugnolle et al., 2005; Traherne et al., 2006). We propose that racial and ethnic differences in allele frequencies in the MHC region of the genome may contribute, at least in part, to the observed racial disparities in asthma.

We leveraged a multi-ancestry cohort and WGS data to identify race/ethnicity-specific genetic variants associated with late-onset asthma. This is one of only a few studies that have conducted race/ethnicity-specific fine-mapping of the MHC region in the context of late-onset asthma in a United States-based cohort (Daya et al., 2021). We discovered several candidate gene variants associated with late-onset asthma that appear to play roles in allergy- and atopy-mediated airway inflammation and hyperresponsiveness. Additionally, we discovered race/ethnicity-specific candidate variants involved in immune pathways.

As additional validation of our findings, the lead variants we discovered are also well-established expressed quantitative trait loci (eQTL). For all participants, we discovered variants associated with both innate and adaptive immunity, primarily allergy- and atopy (eczema)-prone pathways (Figure 6). The 3'UTR *LY6G5C* variant rs4569 is inversely associated with expression of *LY6G5C* and

TABLE 1 Amino acids analysis results for all, White, and Black participants. HLA amino acid positions with a particular residue were associated with late-onset asthma. We adjusted all regression models for age, sex, and four ancestries.

Amino acid position analysis: *Pooled ancestry: significant p -value = 3.9×10^{-4} ; suggestive p -value = 3.9×10^{-3} . *EUR ancestry: significant p -value = 5.6×10^{-4} ; suggestive p -value = 5.6×10^{-3} .

[†]AFR ancestry: significant p -value = 3.4×10^{-4} ; suggestive p -value = 3.4×10^{-3} .

LY6G5B, which are members of the lymphocyte antigen superfamily *LY6/uPAR* (Loughner et al., 2016), both in lung tissue ($p = 1.8 \times 10^{-43}$; $p = 1.2 \times 10^{-29}$, respectively) and whole blood ($p = 1.3 \times 10^{-119}$; $p = 1.8 \times 10^{-33}$, respectively) (Supplementary Table S4). *LY6* protein has previously been characterized as playing a critical role in inflammatory cell regulation, including activation, proliferation, migration, interactions between cells, maturation of antigen-presenting cells (dendritic cells and macrophages), and induction of cytokines upon antigen challenges due to infection and various environmental stimuli (Lee et al., 2013; Loughner et al., 2016). Additionally, publicly available chromatin conformation data (Hi-C) suggest that *rs4569* is in a long-range distal region that interacts with the *NEU1* gene in mesenchymal stem cells (MES) (Supplementary Table S5). The enzymatic activity of *NEU1* increases the signaling of T helper 2 (T_H2) cells and was found to infiltrate and accumulate in the airways and inflamed areas in murine models during acute asthma attacks and children with asthma after viral infection (Katoh et al., 2010; Pech et al., 2018).

For White participants, SNPs and HLA alleles identified from fine-mapping of the MHC region were also associated with genes that regulate innate and adaptive immune responses, particularly pathways involving atopy-related and allergen-driven airway inflammation and hyperresponsiveness (Figure 6). The lead SNP, *rs55888430*, has been shown to interact with the butyrophilin-like 2 (*BTNL2*) gene in IMR90 and MES cell lines (Supplementary Table S5) (Martin et al., 2017). *BTNL2* has also been associated with atopic asthma in children in Korea, dust-mite-specific IgE response in a Japanese population, and sarcoidosis in a White German population (Rybicki et al., 2005; Konno et al., 2009; Kim et al., 2021). The regulatory role of *BTNL2* was demonstrated in T cell activation and homeostasis as a costimulatory molecule during HLA class II antigen presentation to T cell receptors (Konno et al., 2009). Further, variants identified from the conditional analysis in White participants, namely, *rs116062523* and *rs7754362*, are eQTLs associated with the expression of *MICA/MICB* and *BRD2*,

respectively. *MICA/MICB* and *BRD2* influence the activation and function of natural killer (NK) cells as a potential ligand and through the recognition of epigenetic markers, respectively (Stephens, 2001; Kerscher et al., 2019). Depending on the environment, NK cells can directly and indirectly regulate both activation and inhibition of $CD4^+$ and $CD8^+$ T cells (Vivier et al., 2008; Pallmer and Oxenius, 2016). Recent studies have shown that like $CD4^+$ T helper 1 (T_H1) and T_H2 cells, some $CD8^+$ subtypes, including cytotoxic type 1 and type 2 T cells (T_C1 and T_C2), can also produce type 1 and 2 cytokines (Lourenço et al., 2016). Some studies have shown that T_C2 cells are more strongly associated with corticosteroid insensitivity, persistent airway eosinophilia, severe asthma, and atopic asthma than $CD4^+$ T_H2 cells (Gelfand and Hinks, 2019). For White participants, there was notable interaction and/or transition between innate and adaptive immunity involving NK cell-dependent $CD4^+$ and $CD8^+$ T cell responses. Similar variants (and/or interactions) have not been previously reported in studies of early-onset asthma in a United States-based cohort stratified by race/ethnicity.

For Black participants, the HLA-DRB1*03:01 and HLA-DQB1*02:01 alleles were significantly associated with late-onset asthma. Most HLA II-associated autoimmune diseases are accounted for by HLA-DR2DQ6, HLA-DR4DQ8, and HLA-DR3DQ2 haplotypes, and HLA II alleles are much more diverse or polymorphic in African populations compared to White European populations (Mangalam et al., 2013). The HLA analysis results suggest that for Black late-onset asthma cases, T_H2 and T helper 17 (T_H17) cell-mediated pathways may play a role (Figure 6) (Harb et al., 2021). When inflammation occurs due to the presence of an HLA antibody, cells expressing HLA-DQ and HLA-DR activate $CD4^+$ T helper cells and promote the conversion of functional T regulatory cells (T_{reg}) to T_H17 T cells (Mangalam et al., 2013; Lion et al., 2016). Moreover, the plasticity of T_H17 cells allows the conversion of human T_H17 T cells into cells that produce both T_H2 and T_H17 -related cytokines, including IL-4 and IL-17A, respectively (Cosmi et al., 2011). An intron variant, *rs17198965*, approximately 36,316 bp away from the

canonical transcription start site of HLA-C, had a strong promoter-like signature in lung tissue, bronchial epithelial cells, CD4⁺ T cells, CD4⁺ and T_H17 T cells, and B lymphocytes (cCRE accession ID: EH38E3700474). Further, rs17198965 resides in the binding motif for the transcription factor *EZH2*, which suppresses major MHC class I molecule expression and is crucial for initiating CD4⁺ T cell-associated response upon viral infection (Karantanos et al., 2016).

It is well-established that T_H2 and T_H17 cells mediate airway inflammation. The results of our conditional analyses are consistent with this and further show that the selected variant rs17422797 is associated with increased numbers of both eosinophils and neutrophils ($\beta = 0.04$, $p = 1.43 \times 10^{-20}$; $\beta = 0.03$, $p = 3.65 \times 10^{-18}$, respectively) (Broad Institute, 2021). Mechanistically, exposure to allergens and particulate matter promotes T_H2 and T_H17 T cell differentiation in a manner dependent on the interaction of *NOTCH4* receptors on T_{reg} cells with the Notch receptor ligand, *Jagged 1*, on antigen-presenting cells (Xia et al., 2018; Harb et al., 2021). Previous work has found associations in African Americans carrying *NOTCH4*-associated variants with sarcoidosis, which

involves the formation of inflammatory cells (granulomas) in the body, primarily in the lungs (Adrianto et al., 2012).

African American individuals with asthma have an increased burden of symptoms and increased morbidity and mortality compared to White individuals with asthma and display resistance to inhaled corticosteroid treatment (Barnes et al., 2019). T_H17 is also linked to a difficult-to-treat, steroid-insensitive asthma phenotype (Chesné et al., 2014) and has been associated with difficult-to-control asthma in inner-city African American children and atopic dermatitis in African American individuals (Brown et al., 2017). Our findings propose candidate pathways that may be involved in the etiology of asthma in this population, related to population-specific allele frequencies and potential gene-gene and gene-environment interactions.

For HLA-DRB, HLA-B, and HLA-C, we examined the crystal structures with the highest resolution to determine the presence of functional consequences associated with selected individual residues in some alleles. Residues L37 and L/V38 of HLA-DRB are located in the peptide-binding surface and are in contact with the bound peptide. One of the two residues is also in contact with a helix from HLA-DRA that

TABLE 2 Fine-mapping of the MHC region harboring race/ethnicity-specific signals using sequenced data. We evaluated the joint effects of multiple variants on late-onset asthma with stepwise regression models. Conditional analyses of race/ethnicity-specific lead SNPs identified potential causal SNPs in the MHC region for all, White, and Black participants.

**FIGURE 5**

Analysis of amino acid residues showing their potential ability to bind antigens. **(A)** Atoms in residues 37 and 38 are shown as spheres. HLA-DRA (cyan), HLA-DRB1 (gray), M141 TCR α (wheat), and M141 TCR β (yellow) are shown as ribbons. Residues 37 and 38 are located on the peptide-binding surface. One of the two residues is also in contact with a helix from HLA-DRA that comprises the complex. We created this figure using PDB ID (4x5w); **(B)** Atoms in residues 103 are shown as spheres. HLA-B (gray) and β -2-microglobulin (wheat) are shown as ribbons. The small peptide-binding pocket (lines) is composed of three helices, one of which directly interacts with residue 103 within HLA-B. This residue is present at the end of a β -sheet while in contact with a few hydrophobic residues from the helix above and may be important for maintaining the structural scaffold and creating the binding surface. We created this figure using PDB ID (1K5N); **(C)** Atoms in residues 73 and 90 are shown as spheres. HLA-C (gray) and β -2-microglobulin (wheat) are shown as ribbons. The small binding peptide is in direct contact with residue 73, and residue 90 is located in a loop region just after the helix present on the peptide-binding surface. We created this figure using PDB ID (6JT0).

comprises the HLA complex. In HLA-B, L/V103 is an anchor residue of the helix that comprises the peptide-binding cavity and contributes to the stability of the hydrophobic patch composed of residues L109, V165, L168, and L172. Of the two residues selected from HLA-C, T73 is in direct contact with the peptide-binding surface while residue A90 is located in a loop region adjacent to the helix on the peptide-binding surface.

4.2 Strengths and limitations

The current study has several strengths. First, the collection of next-generation WGS data as opposed to genome-wide microarray-based ChIP-chip data enables access to comprehensive information at an allelic level across the diverse MHC locus. Second, enabled by the ancestry diversity in the PEGS cohort, we took advantage of natural differences in genomic LD across diverse populations to conduct transethnic gene mapping, enabling the prioritization of candidate genes, fine-mapping of functional variants, and potential identification of SNPs associated with disease risk in admixed populations.

Despite these strengths, the results must be interpreted in the context of important limitations. First, the importance of the sociocultural context of the varying results for Black and White subgroups cannot be understated. Race is a social construct correlated with health, economic, and exposure disparities. While socioeconomic status and other aspects of health disparities are important risk factors for many diseases, they are both a component and confounder of genetic associations and require further investigation (Fiscella and Williams, 2004). While genes and their variants are involved in the genetic etiology of asthma, regardless of race/ethnicity, the frequency of variants differs

across strata, thus yielding varying results for significant associations. Additionally, the role of the environment, including structural racism, is crucially important, and gene-gene and gene-environment interactions may contribute to differing associations. Additionally, the small sample sizes of some of the stratified analyses may have affected statistical power, so the results should be interpreted with appropriate caution. Finally, we defined asthma cases using information on self-reported physician diagnoses. Given that asthma can be both over- and underdiagnosed (Aaron et al., 2018), this represents a potential confounder.

5 Conclusion

In this study, we explored the pathological role of genetic variants within the MHC region in late-onset asthma due to their critical importance in immune function/response and highly polymorphic nature. Our results suggest interesting parallels and contrasts in the genes and pathways that are associated with asthma dependent on race/ethnicity. The association of HLA II-associated genes and T_H2-related genes with asthma regardless of race/ethnicity may support a basic “minimum requirement” immune component to asthma that comprises increased susceptibility to sensitization and T_H2 activation. Various polymorphisms, depending on ancestry, may reflect stochastic genetic events (such as different allele frequencies) in populations but mechanistically induce similar effects. In contrast, in our cohort, we found a strong association between T_H17 pathways and late-onset asthma in Black participants. Our findings have important clinical implications because knowledge of race/ethnicity-specific

Frontiers in Genetics

Highlights genetic and genomic inquiry relating to all domains of life

The most cited genetics and heredity journal, which advances our understanding of genes from humans to plants and other model organisms. It highlights developments in the function and variability of the genome, and the use of genomic tools.
